A great number of minor disputes arise in all parts of the empire. Thus the other day at Berlin a rich widow founded an institution for the benefit of her employees and laid out £10,000 for this purpose. But in practice the medical attendants did not receive more than 6*d.* per consultation. Doubtless this widow lady is deeply indebted to her employees, who by their work have built up her fortune, but the medical men are not in the least indebted to them. Therefore, they have inscribed this institution on their list of places where offers of employment are not to be accepted. Altogether, a reference to the medical press will show that throughout the empire there are generally more than 100 different places where members of the profession are warned not to accept employment. In the majority of these numerous disputes it is only some one institution that is affected, and the fate of not more than one or two medical practitioners is at stake; but at times, on the contrary, there is a large strike. Of these more serious struggles the present strike at Cologne is a notable example. The free choice by the patient of his medical attendant is the chief point at issue. In Germany, as in France, this is the principal cause of most of the disputes. In speaking of the Compulsory Insurance Law the word *Cassa* (Fr., caisse; Ang., cash) is generally employed. It is the *Cassa* which engages the services of medical men and pays them. Thus the *Cassa* is a sick club, or rather is the committee that collects the funds of a sick club according to the Law on Compulsory Insurance, and effects the necessary payments. The medical officer is not paid according to the service he actually renders, but according to the number of persons he has on his books. He receives from 4 to 5 marks (or shillings) per member per annum. This is the same sum as is paid in England by the better class of clubs and friendly societies, but there is this great difference, the German practitioner obtains the entire sum; there are no deductions. In England the medical practitioner has often to supply medicaments as well as advice, and that costs him from a quarter to a third of his receipts; or the members of a club pay 4*s.* or 5*s.* a year, but the provident dispensary, club, or society takes this money, pays for drugs and working expenses out of it, and only gives the balance to the medical practitioners. Thus when some years ago I looked into the accounts of the Leicester Dispensary I found that of the 4*s.* paid by the members the medical officers only received 1*s.* 10*d.* Nothing of this sort exists in Germany; from 4 to 5 marks a year may be only a small sum, but in any case, such as it is, the German practitioner receives the sum net—that is, without any reduction whatsoever.

In Cologne there are some 400 medical practitioners, and of these about 80 were employed by the local sick clubs. There were 120,000 workmen inscribed in the Cologne *Ortskrankenkassen* and 20,000 families. If we estimate the families at an average of five members each we get a total population of 220,000 enrolled in these sick clubs, among whom medical practitioners cannot hope to obtain a private patient. In some towns which are purely industrial centres and where there is not a large residential and tourist element as at Cologne, the proportion of the population enrolled in sick clubs amounts to 80 per cent. This is especially hard in regard to the families; the payment is 15*s.* per annum per family, which, on an average, means a good deal less than 5*s.* each person, and it is the women and children who very generally require more attendance than the men. But if this pay is small it is certain. In England the situation is seriously complicated by the difficulty of collecting the money and the cost of paying the collectors. In Germany the employer deducts from his workmen's wages the 1 to 2 per cent. of their wages which they have to contribute to the sick fund, while he is by law compelled to add half as much as their contributions amount to, so that two-thirds are paid by the workmen and one-third by their employers. The principle of self-administration prevailing throughout, the management is mainly in the hands of elected representatives of the workmen, aided by the contributing employers and acting under the supervision of the public authorities. So far as possible there are sick clubs for each particular trade, as, for instance, the Builders' Sick Club or the Miners' Sick Club. Management is much easier when all the members have similar risks due to the conditions of employment. The managing boards or committees, as a rule, prefer engaging medical officers themselves. They want the medical officer to be their servant. They want to order him about and reprimand him when they feel so disposed, and the medical profession object to such a state of affairs. They claim that the only persons they have to consider are their patients, and will not tolerate the interference of a committee of workmen standing between them and their patients. The law has decided that all workers who do not earn more than £100 a year must insure against sickness, and has established the necessary machinery for carrying this out and for effecting the necessary payments. But the law leaves the patient free to seek the advice of any medical practitioner who is willing to attend him for the payment which the sick clubs are able to give. At Cologne, however, the sick clubs selected from 80 to 100 practitioners and compelled their members to consult these men and none other.

In 1903 the Deutscher Aerztevereinsbund held its congress at Cologne, and having passed resolutions in favour of securing for the patients the free choice of their medical advisers, called upon the local medical societies to make an effort in this direction. Great enthusiasm was displayed in the cause. Some of the largest sick clubs might have had as many as 20 medical officers in their service, so the members of these clubs had a comparatively large choice of medical advisers; other clubs, however, had only two medical officers, and some only one, so that the members of these clubs had no choice. But by throwing this club practice open to all the medical men of the town the patients, whether belonging to large or to small clubs, would be able to choose from among about 300 medical practitioners. Nevertheless the administrators of the sick clubs would not accept this principle, and ultimately, in 1904, a general medical strike was declared. The strike was to secure for the public the free choice of medical advisers, and for the medical advisers a uniform annual payment of 5 marks per member of the sick clubs. The whole of the medical staff of the clubs joined the strike, and this was all the more remarkable as the object to be attained meant a reduction in their income.

The sick clubs at once set to work to import medical officers and succeeded in securing the services of from 32 to 35 practitioners. They were engaged at a fixed salary, varying from 5000 to 8000 marks per annum. Fortunately for the medical profession the Government has set a limit to the amount of work a medical man is supposed to do, and it is the law that no medical practitioner shall have more than 2000 members of a sick club on his list. Consequently the Government interfered and ordered the committees of the sick clubs to come to terms with the members of the profession so as to secure the services of a sufficient number of medical officers. A five years' agreement was then drawn up with the local society of the Cologne practitioners. The payment of 5 marks per member and the free choice of medical adviser was the accepted basis of the agreement. Thus and in consequence of the intervention of the Government the strike was fully successful. But there remained a sore point—the imported medical men. It was very essential to get rid of them, and it cost a great deal of money to persuade them to go. They had to be compensated to the extent of from £400 to £720. However, with the exception of four or five they all accepted and went. But for some years the medical practitioners of Cologne had to sacrifice a considerable part of the 5 marks they received from the members of the sick clubs so as to provide the means to compensate the imported practitioners and send them out of the city.

Unfortunately the arrangement was only valid for five years and it came to an end on Feb. 1st last. Thereupon the sick clubs declared they would go back to the old arrangement, and the medical practitioners on their side replied that in such a case they would have to strike again. But the situation was no longer favourable. The strike was not so unanimous, as 14 medical practitioners did not agree that it was necessary to strike, and, on the other hand, the sick clubs were able to import a much larger number of medical officers. In a very short time, by making offers of from £300 to £500 per annum, they were able to import more than 60 practitioners. The strike in 1904 only lasted four weeks; the present strike has already lasted as many months. The Government has now no legal reason for interfering, as in the present instance the sick clubs have secured the services of a sufficient number of medical officers. Thus matters have reached a deadlock. The chief hope is that some of the imported men will grow tired of the ignominious position they occupy. Of course, they are ostracised by the whole profession. Deputations from the medical societies constantly call on them and remonstrate. They excuse themselves by pleading poverty and want of practice. A few deny the principle of the free choice of medical advisers and try to argue that it is not a good principle. But as some of these men have already proved failures as practitioners, the hope is entertained that the members of the sick clubs will themselves get dissatisfied and clamour to go back to their old medical advisers, the medical practitioners they themselves selected, instead of being as at present forced to consult imported failures. Some attempts have been made to rouse the members of the sick clubs, but in Germany the workmen are very quiet; they follow meekly their leaders and rarely venture to criticise and take their own business into their own hands. During the five years of the agreement following the strike of 1904 a working man of Cologne could select any one out of 300 practitioners to attend to him when ill. Now he must content himself with the service of the man imposed upon him.

The medical union is making a good fight with this argument. For the moment the struggle goes against them, but mainly because it is limited in extent so that it has been possible to secure the services of a sufficient number of imported practitioners. If, however, a similar contest broke out simultaneously in several large centres, then considering that 23,000, that is nearly all the medical practitioners of Germany, are enrolled in the great national medical union or Verband, the supply of imported men might well become altogether insufficient. In any case, the German medical profession is giving a good example of solid organisation and of solidarity.

Death of Eminent Foreign Medical Man.—The death is announced of Dr. Gustav Christ-Lott, professor of gynæcology and senior physician to the Gynæcological Department of the Polyclinic, Vienna.

BRISTOL AND THE WESTERN COUNTIES.

(From our own Correspondents.)

The British Dental Association.

The annual meeting of the Western branch of the British Dental Association was held at Clifton on July 16th and 17th. There was a good attendance of members. The annual report stated that the branch had now 124 members. The financial statement was satisfactory. Mr. T. Taylor Genge gave the presidential address, in which he alluded to the subject of the anæsthetics Bills. He said that they were all doubtless of opinion that some legislation should be enacted to ensure the administration of anæsthetics by none but skilled and qualified persons, but legislation which was at present under consideration was certainly very unfair to the future licentiate in dental surgery, who from the training he received should certainly be allowed to administer nitrous oxide gas. To deprive him of doing so would not be to the best interest of the public, and would be neither just nor expedient. The annual dinner took place at the Clifton Down Hotel. It was decided that the next annual meeting should be held at Plymouth, with Mr. G. R. Brittan as president.

The Medical Officer of Health of the County of Somerset.

Dr. William G. Savage has been appointed medical officer of health and chief medical inspector of schools for the county of Somerset at a salary of £700 per annum. Dr. Savage has been medical officer of health of Colchester since March, 1903. He has also held the appointment of bacteriologist to the Cardiff Public Laboratory. For the past three years he has been specially employed under the Local Government Board in carrying out investigations upon food poisoning and the bacteriology of milk.

Memorial to the late Mr. B. L. Powne.

The members of the friendly societies of Chard and the district have placed a handsome granite monument in the Chard cemetery as a memorial to the late Mr. Benjamin Lamb Powne, M.R.C.S. Eng., L.S.A. Mr. Powne had been for many years in practice at Chard, where he was medical officer to the first district of the Chard union and workhouse, and also held several club appointments.

Hospital Saturday in Plymouth and Devonport.

July 17th was observed in Plymouth as Hospital Saturday, when collections were made for the South Devon and East Cornwall Hospital. The hospital at the close of 1908 had a deficit of nearly £3500, and the committee has issued a strong appeal for funds. An effort is being made in Plymouth to exceed the record amount previously raised for the Fund, which in 1895 was £748. July 17th was also observed in Devonport as Hospital Saturday, and a special endeavour was made by the Working Men's Committee to secure a much-needed augmentation of the funds of the Royal Albert Hospital.

The University of Bristol.

Sir Isambard Owen, whose appointment to the Vice-Chancellorship has delighted those interested in the University, has resigned the Principalship of Armstrong College, Newcastle-upon-Tyne. The resignation was accepted by the council of the College with expressions of regret, with thanks for help given during his tenure of office, and with congratulations on his new appointment.—At a meeting of the council held on July 23rd Professor J. Michell Clarke, M.A., M.D. Cantab., F.R.C.P. Lond., was appointed Pro-Vice-Chancellor of the University of Bristol.—The committee formed for the purpose of providing a hall of residence for the women students of the University of Bristol announce that, mainly owing to the generosity of two ladies unconnected with Bristol (one of these, besides making a large contribution, has guaranteed a sum of £2000), they have been enabled, with the aid of a grant from the University, to purchase Clifton Hill House for their purpose. The necessary alterations are now being made, so that students may be received at the beginning of next term in October. A further appeal for contributions will be made in the autumn to enable the committee to complete the equipment of the hall, to repay the guarantee, and to fulfil their promise to the University to maintain the hall for a period of two years from next October. The treasurer of the fund is Mr. Hugo Mallet of Goldney House, Clifton.—The men lecturers' committee has just issued a report of the past term's work. This report, which refers to no less than 17 separate undertakings, contains many things already alluded to in previous letters. Mention should, however, be made of one or two points. Very full recommendations as to academic costume are included; these have been drawn up after a commendably [illegible] in use at the various [illegible] sermons, the com- [illegible] of three sermons to [illegible] in the large hall of [illegible] udents' Handbook is to be prepared, and a scheme for the circulation of reprints is recommended as the best method of publishing the scientific research of the University in an official form. A specially appointed committee is collecting information relative to the foundation of a University settlement.

Bristol Museum.

On July 14th a new "Greville Smyth" room was opened in the museum by Lady Smyth, who has given the collections of insects made by her husband, the late Sir Greville Smyth, as well as £2000 for the furnishing of the room in which they are now housed. The Lord Mayor moved a vote of thanks to her for her "splendid and welcome gift to the museum," which was seconded by the [illegible] istol [illegible] that [illegible] hich the University will benefit by a ready access to this large collection of specimens.

Bristol School of Industry for the Blind.

Ever since 1793 Bristol has provided a school for its blind citizens. In 1803 the original small undertaking passed into larger premises; and in 1838 into the buildings which, occupied till now, will shortly pass into the hands of the University. The school is now to be transferred to much larger buildings at Southmead, on the northern boundary of the city. On July 12th the foundation-stone of these buildings was laid by Mr. Joseph Storrs Fry, after a short dedicatory service. The site includes 12¼ acres of land, and the premises in process of erection will provide a resident school and technical institution for 100 pupils. In addition, workshops for 100 men and women are to be provided in the city, with a shop for the sale of the goods made. A sum of between £25,000 and £30,000 is needed in addition to that realised by the sale of the old premises.

Bristol Port Sanitary District.

The medical officers of health of this district have issued their report for 1908. Ships arriving in the port during the year brought ten cases of enteric fever and four of dysentery but none of cholera or plague. A number of data as to the amount of food, including animals, imported into the port of Bristol during the year are given, and the regulations with regard to food inspection, made obligatory by recent legislation, are detailed. An account of such arrangements as already exist for food inspection follows, with recommendations that a port inspector of foods should be appointed to have the oversight of the food imports discharging at Avonmouth and the other docks, as well as of the slaughter-houses at Avonmouth.

July 27th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

SINCE the close of the summer term great headway has been made in the transference of the departments of physics and chemistry to the new buildings at Bournbrook, and the [illegible] are to give more room to [illegible] physiology, and materia [illegible] ised space for the pathological museum, are being rapidly pushed forward, so that everything may be in working order for the commencement of the winter session. It is rumoured that there will be keen competition for the Chair of Zoology, rendered vacant by the death of Professor Bridge, and it is expected that the appointment will be made in September.

The City Sanatorium.

The Salterly Grange Sanatorium was opened on Jan. 7th last, and it appears from the report of the health committee that the results gained during the intervening period are very promising. From Oct. 27th, 1908, to June 30th, 1909, Dr. J. Douglas Stanley, who was appointed to select suitable cases, examined 207 patients, of whom 157 were rejected and 50 were passed for treatment. Those rejected were either in too advanced a stage of phthisis or their family history and constitutional condition were so unsatisfactory that they were unlikely to benefit by the treatment. Forty-nine cases were received at the sanatorium, nine left for various reasons before the completion of their treatment, nine were discharged, and 31 patients were still in the sanatorium at the end of the half year. Of the nine discharged patients eight were apparently cured, and one showed no improvement. Dr. Stanley reports that he has not seen all the patients who have been under treatment, but those he has examined show very satisfactory results, some having lost all signs of phthisis and others being so much better that there is every hope that they will recover completely.

Tuberculosis and Milk-supply.

Whilst our health committee will welcome and take part in any national scheme for the eradication of tuberculosis amongst cows it proposes to act in advance of a general movement, and has under consideration a scheme which, with the approval of the council, it will put in operation in the ten-mile area around Birmingham. If the scheme is approved the dairymen within the area who send milk into the city, who have sanitary cowsheds, and who undertake to separate the healthy from the diseased animals and gradually dispose of the latter, will be provided with the necessary veterinary assistance for testing all their dairy cows. It is estimated that in the first year the scheme will cost £120, and that the cost will gradually increase to £300. By the expenditure of such comparatively small amounts the committee hopes to demonstrate that the dairy herds can be kept free from tuberculosis, and it also hopes that as the cow-keepers become familiar with the methods and see the good results, increasing numbers of them will fall in with the scheme and take the necessary steps to ensure success.

The Hospital Saturday Fund.

Unless the later indications prove to be incorrect, for the first time in its 37 years' history the Hospital Saturday Fund will not reach the level attained in the previous year. Last year 2084 contributors subscribed £20,163 7*s.* 6*d.* This year the number of contributors has fallen to 2045 and the total contributions, according to the last published statement, to £19,040 12*s.* 2*d.*, a decrease of somewhat over £1122. The result is disappointing, yet it is neither unexpected nor surprising, and considering the unsatisfactory state of trade we may be glad that the diminution is not greater. Yet as one passes along the streets one cannot help noticing that the crowds waiting to go into theatres and music halls are not appreciably diminished. Such crowds consist largely of the classes which make most use of the hospitals and it would appear that a little sacrifice of pleasure might have prevented the set back to the Fund which gives so much in return to those who still appear to have money to spend on less worthy objects.

The Health of Warwickshire.

Dr. A. Bostock Hill's annual report upon the health of Warwickshire is very hopeful in tone and certainly the results recorded must be admitted to be good as contrasted with those which existed in the past, if they are looked at purely from the point of view of a health officer. Ten years ago the population was 352,000 and it is now 400,000; during the same period the general death-rate has fallen from 15·93 per 1000 to 12·8 per 1000, and the infantile death-rate from 142 to 100 per 1000; consequently, as a result of the improving conditions an average of 487 lives per annum have been saved, calculating on the population of the middle period and the general death-rate. On the other hand, the birth-rate has fallen and last year it was only 25·7. Whilst the average death-rate is, on the whole, fairly satisfactory, it has been, and still remains, distinctly high in some districts, particularly in Bulkington, where it is 20 per 1000, and Dr. Hill suggests that an investigation should be made regarding the cause of this comparatively high rate.

July 27th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Health Congress at Leeds.

THE Health Congress held recently at Leeds has been reported at satisfactory length in the newspapers, more especially in the excellent journals of the great Yorkshire towns, and since the utility of such a congress largely depends upon the public attention which it receives the interest taken in its proceedings by the daily press cannot fail to have been of service to sanitary progress. On such an occasion any new *ex cathedrâ* pronouncements in hygienic science or preventive medicine can hardly be expected, and the Leeds meeting was not, in fact, particularly notable as a scientific conference, but it was of great value in bringing the medical men engaged in public health studies into contact with the rapidly increasing number of volunteer lieutenants and non-commissioned officers in the national sanitary army, and also with those public-spirited members of town councils and sanitary authorities who appreciate to the full their responsibilities in the health of their fellow citizens and are anxious to hear the studied opinions of experts for their future guidance. On the other hand, the experts themselves cannot fail to gain some profit from the views of such intelligent and philanthropic laymen as devote their time and money to the improvement of the public health, and more especially of those engaged in municipal administration who have the responsibility of spending the ratepayers money in the way most advantageous to their towns. The importance of such coöperation was recognised to the full by the organisers of the Congress, who devoted a section to representatives of municipalities, in which medical officers of health had the opportunity of meeting aldermen, bailies, councillors, engineers, and architects, all of whom were able to give their views in the course of such instructive discussions as arose out of the address by the Lord Mayor of Leeds (Alderman F. J. Kitson) on the sanitary evolution of that city. In this debate Mr. Percy Robinson made some trenchant remarks on town planning in relation to health, in the course of which he accused our nation of a lack of "that artistic spirit and civic pride which is so characteristic of our continental neighbours," and urged the formation of advisory committees of architects, artists, representatives of educational and other bodies to assist municipal authorities in the development and rebuilding of city areas. Mr. F. E. Fremantle, medical officer of health of Hertfordshire, followed this paper with an account of Letchworth Garden City in relation to the Town Planning Bill, in the course of which he uttered a strong protest on the detrimental effect which the present Finance Bill must have on the development of the city. Another section to which particular attention was directed was that devoted to child study, in which the health-workers and home-visitors gave free expression to their experiences. The topic which lies at the root of the public health of the next generation was not confined to this section, but occupied the attention of a plenary meeting of the Congress, which Dr. George Newman, medical officer to the Board of Education, addressed on Child Mortality in Relation to the Health of the State, dwelling particularly on the ill-effects suffered by infants as a consequence of the bad health of their mothers. Dr. Newman considers that all future effective preventive medicine must start with the home and "must deal more with the home than the house," but that the State must do its work by educating parents and not relieving them of their responsibility in their children. He cannot see in compulsory military service a panacea against physical degeneration, for it affects neither the boy, the man who is organically unfit for service, nor the woman, the factor on which the health of the race most depends. "The true and radical method of physical improvement," said Dr. Newman, "is to lay the foundations deeply and broadly upon healthy childhood. ...... By these means we shall, to use Pasteur's noble words, extend the frontiers of life." A discussion that produced some vigorous expressions of opinion was on the training of girls in the duties of motherhood, which Colonel Harding, the President of the Congress, took to be the main object of a woman's education. One speaker seemed to trust the mother's "instinct" to do what is right for her baby without being taught, but others, notably Alderman Broadbent of Huddersfield fame, strongly advocated the practical teaching of girls in the proper methods of caring for live babies, and he expressed thorough disgust with those teachers who are content to set schoolgirls to wash rubber dolls. Mrs. Scharlieb, M.D., contributed a useful plea to this discussion, in which she showed her appreciation of the unstable psychology of many adolescent girls, especially with regard to their romantic friendships, and urged that "the conspiracy of silence amongst school teachers and parents should be ended and boys and girls taught to realise their responsibilities." Another notable paper was Dr. Arthur Newsholme's address to the section of preventive medicine on the subject of communal action against tuberculosis, in the course of which he rebuked those municipalities which "built extravagant town-halls whilst the water-supply of the town remains impure, or provides Turkish baths, as in some towns in Yorkshire, whilst back-yards and streets remain unpaved."

Death of the General Manager of the Infirmary.

The announcement of the sudden death of Mr. T. Blair, the general manager of the infirmary, will be received with great regret by a very large number of medical men, and many generations of former residents will be reminded by the announcement of a genial and courteous officer and of one who always held a high place in their respect and esteem. The following motion, proposed by Mr. Charles Lupton, was carried at the weekly board meeting of the infirmary:—

> The weekly board of the General Infirmary at Leeds desires to record its sense of the great loss which the infirmary has sustained in the death of Mr. Blair, who has held the responsible post of general manager of the institution since March 21st, 1876. Coming as he did when the infirmary was doing less than half the work which it now carries on, he has watched its growth with the utmost interest, and has himself been one of the chief factors in the large measure of success which has been obtained. Ever vigilant in watching expense, and earnest in increasing the efficiency of the institution, his genial manners and personal courtesy have rendered him a valued friend of the members of the weekly board and honorary and resident staff, and have earned the gratitude of the patients with whom he has had to deal. The board desires to express its deep sympathy with Mrs. Blair and the family in their bereavement.

July 27th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Home for Epileptics at Maghull: the Treatment of Epilepsy.

THE annual meeting in connexion with the Home for Epileptics, Maghull, was held on July 17th, at the institution, in the presence of a large gathering, over which the Lord Mayor of Liverpool presided. The report stated that the record of the year 1908 was one of rapid progress, the increase in the number of inmates being no less than 46, owing to the additional accommodation afforded by the new Chilton home for children. There remained in the institution on Dec. 31st, 1908, 259 patients, classified as follows: First-class, 10 males and 2 females—12; second-class, 29 males and 24 females—53; third-class, 103 males and 91 females—194. The admission of the large number of children which the Chilton home would accommodate—at least 40 boys and 30 girls—greatly added to the responsibilities of the management. Not only had regular school teaching, approved by the Board of Education, to be carried on, but in the case of these patients, even more than in that of ordinary children, it was necessary to give at least elementary industrial training. As time went on the question would arise as to what is to be done with them on reaching the age of 16 years. In cases where they were paid for by their friends or by boards of guardians, no doubt they would be allowed to remain in the institution. In other cases this might not be possible, and they would return to ordinary life without such a preparation as the home might give them if a few years longer could be spent under its treatment and training. This was an important question to be considered by public authorities.

The Royal Commission on the Care and Control of the Feeble-minded went so far as to recommend in its report that persons who could not take a part in the struggle for life, owing to mental deficiency, should be afforded by the State such special protection as might be suited to their needs, and that this protection should be continued as long as was necessary for their good, in their own interest and in that of the community. This would apply to a considerable proportion of epileptic persons, and the needful care and [illegible] than during [illegible] nent of those [illegible] years during [illegible] onfirmed the [illegible] with medical treatment adapted to the individual patient and suitable nursing when required, but still more with the continuous supervision of trained nurses and attendants, the most important factor was occupation and the exercise of mind and body which it brought. No healthy person could remain idle with impunity without deterioration of mind and body. Still less could a person afflicted with epilepsy do so. Naturally sluggish as a rule, the patients require the stimulus of steady duties, which must be performed, and under such stimulus they almost invariably improve in mind and body. In all departments where there were continuous duties involving responsibility a certain number of paid offices had been created for the purpose of giving encouragement to those holding them. In this way a sum of £94 odd was paid to patients engaged on the farm and nearly £68 to those engaged on certain general work, altogether reaching over £162. Although the rate of remuneration was necessarily small the good result was manifest, as the system had the effect of stimulating all the patients through the general desire which exists to qualify by steady work for the status of a paid worker. Owing to the crippled state of the finances the current demands for necessary additions and extensions had made the liquidation of the £2842 due on the children's home an impossibility. This is much to be regretted. The Lord Mayor alluded in complimentary terms to the management of the home and [illegible] the treatment of the inmates. [illegible] supporting the adoption of the [illegible] ing with epileptics at Maghull had been copied in London. The fact that epilepsy caused insanity was a point of view of great importance, and their object was to prevent mental deterioration, if they possibly could, by taking the children at an early stage and placing them under the most favourable conditions possible. He ventured to assert that many of those demented epileptics would not have been in the condition they were if they had been treated early in a colony [illegible] Rhodes (Manchester), [illegible] tee, said that in the [illegible] r individuality more [illegible] and whether it was epilepsy or insanity the colony system, such as existed at Maghull, was the right style to build upon. By providing such places a splendid work was being done in training patients to be as useful as possible. He asserted that from 15 to 20 per cent. of the prisoners in the gaols to-day were either epileptics or mentally deficient. It was cheaper to maintain them in colonies than in gaols.

Infectious Diseases in Liverpool.

At a meeting of the port sanitary and hospitals committee of the city council held on July 22nd the medical officer of health reported that during the two weeks ending July 21st the number of cases of infectious disease reported and the number removed to hospital were as follows: scarlet fever 114, removed 80; diphtheria 35, removed 21; typhoid fever 8, removed 8; measles 65, removed 31; totals, 222 and 140. The total cases in the city infectious hospitals were as under: scarlet fever, 509; diphtheria, 73; typhoid fever, 21; phthisis, 51; measles, 101; isolation cases, 78; total, 833. The experience in Liverpool, as in other large towns, is that, simultaneously with the closing of the schools for the holidays, infectious disease begins to decline. For the last three months scarlet fever has been very prevalent in the city, but this week's statistics show that the fresh cases reported had fallen to 52. A month or six weeks ago the new notifications averaged over 100 a week. At the present time there are 509 scarlet fever cases in the infectious hospitals, which is a considerably decreased total. Over 700 had been in hospital for some weeks, amounting to less than 1 per 1000 of the population. It would thus appear that the school is the chief agent in the spread of that disease.

Liverpool Convalescent Institution at Woolton.

The thirty-fifth annual meeting of the Liverpool Convalescent Institution was held on July 10th. The Lord Mayor was in the chair, and amongst those present were the Bishop of Liverpool and Mrs. Chavasse and Sir William H. Tate. The report was very satisfactory. This magnificent resort for jaded and weakly persons renders a service of immeasurable value to the city in enabling enfeebled bread-winners of working-class families to be restored to health and vigour. The Bishop remarked with his usual vigour on the benefits and the picturesque surroundings of the home, and described it as a paradise outside and a palace of delight within.

Payments for Maintenance in the City Infectious Hospitals.

The port sanitary and hospitals committee, after due deliberation, is unable to recommend that a charge be made for patients taken to the corporation infectious hospitals. An exhaustive inquiry into the matter has convinced the committee of its impracticability, because a residence is not always a clue to the occupant's means, because patients or their friends claim the right of the use of the hospitals as ratepayers, and because inquiries, unless very carefully conducted, "tended to obstruct the objects of the committee in effecting the isolation of the sick." Other large cities have had a similar experience, and have abandoned the idea owing to the difficulties in collecting payment.

The Liverpool Dispensaries.

The committee of the [illegible] being obliged to rebuild the premises in [illegible] at an estimated cost of [illegible] William Hartley a cheque for [illegible] towards the cost [illegible] promise of £500 from [illegible] at the end of Aug [illegible] of the Liverpool [illegible] the Liverpool working class.

July 27th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

The Departure of Sir Isambard Owen.

THE appointment of Sir Isambard Owen to the Vice-Chancellorship of the Bristol University has been notified. This means that the distinguished Principal of the Armstrong College (formerly the Durham College of Science) of Durham University will resign the position which he has held here since 1904. It may be remembered that Sir Isambard Owen gave up the actual practice of medicine in London, where he was physician to, and lecturer in medicine at, St. George's Hospital, to turn his complete attention to educational matters, in which he has always interested himself. He has been Deputy-Chancellor of the University of Wales since 1895. Latterly, apart from his actual superintendence of the affairs of Armstrong College, he has been energetic in connexion with the University of Durham Bill. His departure will be regretted exceedingly in Newcastle-upon-Tyne, where he has made many friends by reason of his geniality and extreme earnestness, and it is greatly to be hoped that his new appointment will not mean the withdrawal of his valuable opinion and advice concerning things educational in the north of England.

Feeding of Dairy Cows.

The Durham county council education committee has issued a report containing the results of experiments carried out at Offerton, Durham, by Mr. S. H. Collins, M.Sc., of Armstrong College, and by Mr. F. P. Walker, B.Sc. The experiments, which were conducted during the summers of 1907 and 1908 and the winter of 1907, were directed to two ends: firstly, to determine the result on the milk of feeding with brewers' grains; and secondly, to show what possibility there might be of the transference of boric acid from the food of cattle to their milk. As regards the first the conclusions drawn are: 1. That a moderate amount (20 pounds) of brewers' grains per day increases, for a certain time at any rate, the yield of milk, and that this period of increase has its limit. A corollary of this is that the practice of changing the diet of the animals is a good one. 2. There is no appreciable diminution of the fats under the diet, that is, as to the daily yield, but the fat of the morning yield is lowered more frequently. 3. No change was noted in the non-fatty solids. 4. There was no notable change in the live-weight of the cattle. It must be remembered that these results were obtained when the grains were used in moderate quantities only, with good additional artificial food-stuffs. As regards the conclusions under (2)—the lowering of the morning fat—this would mean that brewers' grains are not to be recommended, especially when the 3 per cent. standard is also taken into consideration, but for ordinary dairy cows it would appear that such grains may safely be used, the stock being otherwise well fed. The second group of experiments is also interesting, the point of these being to answer the question, "Can boric acid get into milk as the result of feeding cows on food containing boric acid?" These investigators state that it can, but they add that the amount is so small as to be negligible from the point of view of its preservative properties. If the milk contain more than 0·1 per cent. of the acid this last has probably been added. If present in less quantity than 0·01 per cent. the food of the cow may be responsible. Between these two limits is uncertainty as to its origin, but inasmuch as 0·25 per cent. boric acid is needed to keep milk sweet there should be no doubt as to whether the acid is derived from the food or has been added to the milk. The experimenters state that, using small quantities of boric acid in the food, one-sixtieth part reaches the milk. They further add some observations which raise the old difficulty of dealing with milk samples—viz., how long may milk stand at rest without making the part withdrawn differ markedly from the bulk? A large vessel with a tap at the bottom was used and samples taken from the top of the vessel and from the tap at various times. They concluded that in fairly high temperatures the samples obtained after only a few minutes' rest are useless as representing the bulk; with lower temperatures the error is not so great.

Durham University.

A convocation for the purpose of conferring degrees was held at the Durham University College of Medicine in Newcastle-upon-Tyne on July 24th. The degrees were conferred by the Sub-Warden, Professor F. B. Jevons. The majority of the degrees conferred were medical, and the recipients were the successful candidates from the recent summer examinations held in the University. The candidates were presented by Sir George Hare Philipson (President of the College) and by Professor F. Page.

July 26th.

SCOTLAND.

(From our own Correspondents.)

The Chair of Surgery in the University of Edinburgh.

As was intimated in The Lancet last week Mr. Henry Alexis Thomson was selected by the Board of Curators to fill the Chair of Surgery vacated by Professor J. Chiene. Mr. Thomson graduated at Edinburgh in 1885; four years later he took the degree of M.D., obtaining a gold medal for his thesis on "Tuberculosis of the Bones and Joints." He has from the outset of his career devoted himself to surgery and at the time of his appointment to the Chair of Surgery held the post of surgeon to the Deaconess Hospital and assistant surgeon to the Royal Infirmary. He has made many valuable contributions to the literature of surgery, but the work which has made his name most widely known is the "Manual of Surgery," which he published in conjunction with his colleague, Mr. Alexander Miles. This work is used largely in the British and American schools and has reached a third edition. Mr. Thomson has been a teacher and a lecturer to students almost from the time he graduated and has for years been an examiner in surgery, while his application was supported by testimonials from well-known surgeons in Britain, America, and on the Continent, who bore witness to the excellence of his surgical work and to the place he held in the estimation of his surgical *confrères* throughout the world. Mr. Thomson is 45 years of age, and has thus the prospect of many years of work before him, and the opportunity of not only upholding, but of adding to, the honour and dignity of the chair he has been selected to occupy.

University of Edinburgh: Medical Graduation Ceremonial.

The medical graduation ceremonial in the University of Edinburgh was held on July 23rd, the chair being occupied by the Vice-Chancellor, Principal Sir William Turner, K.C.B. While the ceremonial at this date is mainly given over to graduation in medicine it is not confined to this, and considerable additional interest was added to the proceedings by the presence and the conferring of the degree of LL.D. on the Right Hon. George Wyndham, M.P., the Lord Rector of the University. This honorary degree was also conferred on Madame Curie *in absentiâ*. After these had been conferred the Dean of the Faculty of Medicine presented 59 men and five women for the degree of M.D. Seven of the men received gold medals for their theses and one of the women got "highly commended." The degree of Master of Surgery was conferred on two men. Thereafter 93 men and 10 women were presented for the degree of M.B., Ch B. The Ettles Scholarship was awarded to Mr. Robert Coltart Harkness as the best graduate of the year, while the Dorothy Gilfillan Memorial Prize was awarded to Miss Mary Muter Gardner as the best woman graduate. The graduates were addressed by Sir Thomas Fraser, the Promoter, who mentioned that that was the third occasion on which he had addressed the graduates, and that now not one of those remained who constituted the Faculty of Medicine when he first joined it. He referred to the losses the faculty had experienced recently by the death of Professor D. J. Cunningham and the resignation of Professor J. Chiene. He then referred to the advances which had been made in the University during the past 15 years in the encouragement of original research, and said that now higher education by research had established for itself a firm position in their university system its further development might be regarded as assured. Instead of a university being regarded merely as an institution for imparting acquired knowledge, and at which the growth and extension of knowledge were ignored, so remarkable had been the appreciation of the value of scientific research in this country that there were now institutions whose sole function was original investigation. Among the first of these to be instituted were the research laboratories of the Royal College of Physicians, Edinburgh. For the university the ideal was the appropriate combination of both purposes. He referred to the need of new special courses being established, as had been done in public health. Whatever might be the future work of those before him they would recognise that research and advanced study in special departments of medicine merely constituted two of the methods by which the power of observation and judgment might be trained and the mind taught to appreciate truth and to strive to obtain it. Luncheon was afterwards given in the University Union in honour of the honorary graduate, Mr. Wyndham.

IRELAND.

(From our own Correspondents.)

Tuberculosis Prevention (Ireland) Act: Dublin County Council.

At the adjourned quarterly meeting of the Dublin county council, which was held on July 22nd, a communication was submitted from the Kingstown urban district council stating that it had decided to adopt Part I. of the Tuberculosis Prevention (Ireland) Act, 1908, subject to the approval of the county council, and applying for the necessary approval. The provisions of the Act were explained by the solicitor to the council, who pointed out that any sanitary authority could adopt the Act, but that the adoption was subject to the approval of the county council. A considerable amount of discussion followed, and had the effect of eliciting the principal arguments which have from time to time been advanced both for and against the working of the Act's most important clauses. One member expressed the opinion that the meaning of the Act was that people who should be pronounced to have this disease would be banished from society and from their friends for ever. The chairman pointed out that such persons were removed to the most suitable surroundings that science could devise to improve their condition, while in addition to the enormous advantage to the sufferer the public at large were saved from the possibility of infection by contact. Another speaker asked whether any remuneration was provided for the rest of a family in case the bread-winner was pronounced to be a victim of tuberculosis. If there was not, he would be very slow to "put him away." One of the speakers stated emphatically that if the people of Kingstown had been consulted the adoption of the Act would have been opposed by fully 90 per cent. The matter had come on them as a surprise. The secretary of the council then read a resolution which had been forwarded by the Kingstown Municipal Reform Association expressing disapproval of the adoption of Part I. of the Act, and requesting the county council not to sanction it on the grounds that, if enforced, "it would be injurious to the interests of Kingstown as a health resort, and would inflict serious injury on the poor." In the course of the subsequent part of the discussion it was observed that in a chronic case a house would have to be disinfected every week, and the result would be to have the inhabitants branded at once as lepers—and for life. The feeling of the meeting was demonstrated by the decision to postpone the consideration of the matter for 12 months. The discussion and resulting decision are highly instructive with regard to the present state of opinion on the subject in Ireland.

Belfast Lunatic Asylum.

Dr. William Graham, medical superintendent of the Belfast District Lunatic Asylum, has issued his annual report for the year ended March 31st, 1909. Financial tables for the year ended March, 1909, are appended. There were 266 admissions—the same as for 1904—or about the average of the past five years. Among the asylum constituency there are three classes which should not, as a rule, be treated in a hospital for mental diseases. These are the alcoholics, epileptics, and the criminal insane. The first should be, Dr. Graham advises, sent to an inebriate home; the second ought to be treated in colonies; and the third by their presence interfere with the true ideal of a hospital, as they tend to deepen the stigma which despite everything is still attached to asylum life by the popular mind. Having dealt most exhaustively with the causes and treatment of insanity, Dr. Graham gives the history of the year, during which 82 patients recovered and 37 were discharged as relieved. The ratio of recoveries to the total number of admissions was 30·8 per cent. There were no deaths from accident or suicide. The most notable event of the 12 months was the acceptance of tenders for carrying out the villa colony buildings at Purdysburn, the works of which are now in progress. Appended to the report is a most satisfactory memorandum of inspection in December, 1908, by the Government inspector, Dr. E. M. Courtenay.

Belfast and the Tuberculosis Prevention (Ireland) Act.

The public health committee of Belfast has decided to postpone for a time the question of the adoption or not of the Act. A very strong memorial from the Belfast Branch of the Women's National Health Association of Ireland has been presented to the public health committee urging the adoption of the measure.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Relationship of Variola and Vaccinia.

THE question whether variola and vaccinia are or are not modifications of the same pathological process is an important point upon which medical opinion is divided. Inoculation of the human subject with bovine vaccinia is a protection against variola, but does the converse hold good—that is, does inoculation of a cow with human variola protect it against an attack of vaccinia? It appears that the views of the German observers on this subject are diametrically opposed to those held by the French, but M. Kelsch and his scientific fellow-workers have recently suggested an explanation of this singular divergence. The explanation is to the effect that the French experiments have been made with great care, precautions being taken to isolate the animals after inoculation, but the Germans leave them in the cow-houses of the vaccination stations where the proximity of cows already inoculated with vaccinia suffices to bring about contagion. It is therefore not variola which they transmit in this way; it is vaccinia which manifests itself by air-borne contagion. In order to prove this M. Kelsch inoculated three heifers *à blano*—i e., with glycerine only; they were left in the general cow-house and between the sixth and seventh days characteristic vaccinia pustules appeared at the points of inoculation. Now if variola had been inoculated in place of glycerine a success would inevitably have been registered to the credit of the German opinion.

Vaginal Hysterectomy.

At a recent meeting of the Society of Paris Surgeons M. Brochin called attention to the importance which his teacher, the late Professor Péan, attached to vaginal hysterectomy, and he expressed regret that this operation had now fallen into disuse. Professor Péan employed it in the removal of fibromata even when of considerable size, in bilateral inflammations of the adnexa, in metro-salpingitis, in pelvic suppurations, in cancer of the cervix, and in prolapse of the uterus occurring subsequently to the menopause. For small fibromata in particular vaginal hysterectomy was an excellent operation, exposing the patient to the least possible danger; and even in cases of bilateral inflammations of the adnexa, pelvic suppurations, circumscribed cancer of the cervix, and uterine prolapse the operation might be of the greatest value in expert hands. M. Péraire declared himself to be of a different opinion and maintained that there was good reason for this method of hysterectomy being almost completely abandoned in France. With this operation it was not possible to form an opinion as to the state of the lesions, and several dangers were associated with it, such as probability of débris being left behind and the bladder being wounded, infection of the peritoneum, compression of the ureters and intestine, and hæmorrhage. He did not think that vaginal hysterectomy was advisable in either fibroma or cancer or prolapse of the uterus or in pelvic suppuration. In prolapse of the uterus hysteropexy was sufficient, and in the other conditions above mentioned, abdominal hysterectomy was to be preferred, now that successive improvements in the mode of performing the latter operation have rendered it comparatively safe. M. Paul Delbet took the side of M. Brochin, considering vaginal hysterectomy to be an excellent operation in some circumstances. In cases of cancer vaginal hysterectomy was, in his opinion, only a palliative; complete abdominal hysterectomy was the proper treatment, and 12 such operations performed by him had been successful. Vaginal hysterectomy produced less shock and was a suitable procedure in pelvic inflammations which were neither cold nor diffuse (*non refroidies ou mal limitées*), as well as in fibromata not rising more than four fingers' breadth above the pubis and not having too great a transverse diameter.

Legislation Relative to the Use of White Lead.

Both the Senate and the Chamber of Deputies have now passed the Bill regulating the use of white lead until such time as the use of this substance by painters will be entirely prohibited. In workshops, shipbuilding yards, houses in course of construction or repair, and generally in every place where painters are at work, the heads of firms, directors, and managers are bound, independently of the measures prescribed for the health and protection of the workmen, to conform to the new ordinance. At the end of the fifth year following the promulgation of the present law the employment of white lead, of linseed oil containing white lead, or of any special product into which white lead enters will be prohibited in work of any kind whatsoever done by men engaged in the painting trade, whether inside or outside buildings. A regulation of the public authorities, drawn up in accordance with the advice (1) of the consulting committee of arts and manufactures, and (2) of the commission of industrial hygiene will be required for the performance of any special work for which relaxation of the provisions of this law may be required. The inspectors of factories and workshops have instructions to see that the law is enforced, and for this purpose they may enter any of the places mentioned above, with the reservation that if the places in question are habitations (*locaux habités*) the inspectors must previously obtain the permission of the occupants. The new law will be promulgated before the end of the present year. The prohibition of the use of white lead will, therefore, not come into force until Jan. 1st, 1915.

Treatment of Hydatid Cysts of the Spleen.

At a meeting of the Surgical Society held on July 7th several members described the results obtained by them in the treatment of hydatid cysts of the spleen. One of the patients was a man, 52 years of age, under the care of M. Bazy, who approached the tumour by an incision parallel to the external border of the rectus muscle, punctured the cyst, and applied formol to the cavity with subsequent drainage; this was followed by an uneventful recovery. M. Potherat said that in these cases he was generally in favour of splenectomy, which did not appear to him to be objectionable as the gland was already diseased. M. Ricard said that he had operated on a boy six or seven years of age who suffered from an enormous hydatid cyst of the spleen—so large, in fact, that it was supposed to be a hydatid cyst of the liver. The spleen was of normal appearance, but formed a kind of cap to the cyst. In this instance the idea of splenectomy did not occur to him; he reduced the spleen and "marsupialised" the cyst. A second operation had to be performed on account of a hernia consecutive to the marsupialisation. The ultimate result was excellent.

The Academy of Medicine.

A decree has just been issued authorising the Academy of Medicine to accept a bequest of 25,000 francs, the income of which accumulated for three years will serve to found a perpetual triennial prize. This will be called the Potain prize, and will be awarded to the best work on clinical medicine which has appeared during each triennial period.

July 27th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Parliament and Public Health.

AMID the "sound and fury" of the debates that turned the Chamber of Deputies into a bear-garden in the last weeks of the session the "still small voice" of science was occasionally heard in the interests of public health and in vindication of legislative comity. Dr. Gaetano Pieraccini of Florence, for one of whose constituencies he sits as an advanced Liberal and in whose medical school he fills with credit the post of privat-docent in "patologia medicale," put some searching inquiries to the Minister of Agriculture, Industry, and Commerce on the protection of the labourer and the working-man in the discharge of his *métier*—inquiries prompted by the findings of the recent Congress on the maladies incurred in city factories and inland mines. He pointed out that ankylostomiasis—an eminently contagious parasitic disease—has recently assumed a novel development, the germs of which have been imported from America by Italian emigrants returning to their native land. The "lavoratore della terra," already scourged by pellagra and malaria, can ill afford this third perquisition levied on his vitality and strength, and the dictates of economy, as well as humanity, call loudly for his protection from the said pathological exaction, while such indemnity should be assured him as will enable him to meet the expenses of prophylaxis and cure. His Excellency Signor Cocco-Ortu, the Minister above referred to, replied that special studies in the new malady were in progress by a commission under his department and that the prophylaxis urged by Dr. Pieraccini was being considered by the Direzione Generale della Sanità Pubblica, which took its orders from the Minister of the Interior. The "Circumlocution Office," it will be seen, is not unknown in Italy, but let us hope that the persistence and scientific strategy of such sanitary reformers as Dr. Pieraccini will ere long succeed.

The State Provision of Quinine against Malaria.

At a previous sitting Dr. Angelo Celli, another representative of the medical interest in Parliament, and also known and esteemed as professor of hygiene in the Roman school, invited the Government to add to its supply of quinine in the malaria-haunted districts a special preparation for the use of children of tender years, thousands of whom, he showed, fall victims to the disease. Congratulating himself on the augmentation of the money grant to the Red Cross in its anti-malaria crusade, and urging the still further facilitation of the exhibition of the drug, Dr. Celli elicited from Signor La Cava, the Minister appealed to, the reassuring announcement that the grant has this year been augmented by 30,000 lire (£1200). As too often occurs in the administration of money grants, the deflection of a State subsidy to extraneous uses is (Dr. Celli was sorry to show) not unknown in the malarious districts, and steps are, on his initiative, to be taken to secure the bestowal of the money on none but the parties for whom it is intended. This malversation notwithstanding, the disease is in continuous diminution—a result which, Dr. Celli thinks, will be still further in evidence when, to the preparations of quinine already in use, the tannate is added—a form of the drug which is by far the most easily digested, while it has none of the adventitious disadvantages of those combinations of arsenic and iron in which it is too often exhibited.

Births, Deaths, and Marriages.

The number of infants born alive in 1907 (the last statistical year) was 1,062,233; or 31·45 per 1000 of the inhabitants, a figure rather below that of the two years preceding. The greatest number of births was in January (100,491), the smallest in December (80,346). The number of male children exceeded that of the female—545,994 of the former to 516,339 of the latter—i.e., 1057 males for every 1000 females. The illegitimate births and foundlings amounted in all to 55,571, of whom 33,554 were recognised in the act of birth by at least one of the parents. The total of infants born dead in 1907 was 48,023. The multiple births were 12,963, the majority being in the Emilia, the Marches, in the Venetian territory, and in Latium. In 1907 there died in all Italy 700,333 individuals—i.e., 20·73 per 1000. In the great cities the mortality was somewhat higher than in the rest of the kingdom. The number of deaths is every year lower than that of the births, thus explaining the steady increase of the population. The influence of the seasons on mortality is heavy from December to March, diminishing thereafter to June, while accentuating itself in the two succeeding months of the summer and being mildest in the two succeeding months of the autumn. The deaths in 1907 were distributed in the proportion of 354,109 males to 346,224 females, or 102 of the former to 100 of the latter. Infantile mortality is in appreciable diminution, in keeping with the improved public hygiene. The marriages contracted in 1907 were 260,104—i.e., 7·70 per 1000 inhabitants. In 1906 the figures were 7·77 and in 1905 7·67. In the great communes the nuptial rite is usually rarer than in the country districts—the month most propitious to it being February with 29,770 marriages, and the least so being August with 14,430. The mean age of the couples in 1907 was, for the "celibi," that of 27 years 3 months; for the "vedovi" (widowers) 44 years; for the "nubili" (marriageable) 23 years and 9 months; and for the widows 41 years and 5 months. "Analfabetismo" (inability to read, write, or cypher) in married couples is diminishing. In 1907 the marriage lines were underwritten by 186,275 bridegrooms and 155,403 brides; not underwritten by 73,229 of the former and 104,701 of the latter. In 1872 the figures were the following: bridegrooms who underwrote the marriage lines, 88,589; those who could not, 113,772; and for the brides respectively, 50,017 and 152,344. Piedmont and Lombardy show fewest "analfabeti," the southern provinces most, principally in Reggio Calabria, Cosenza, and Catanzaro.

July 24th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Accidents during Anæsthesia.

A DEPLORABLE misadventure happened recently in one of our large hospitals, a person who had applied for advice in the out-patient department dying under anæsthesia, which had been induced for a minor operation. This sad occurrence has caused the Home Secretary to issue an instruction to all boards of health and hospital boards, calling their attention to the necessity of laying down definite uniform rules for similar purposes, and as a consequence all medical men and medical corporations have received the following official communication: "In order to prevent accidents to patients during general anæsthesia the following points must be strictly adhered to. Nobody may give chloroform or any other anæsthetic to a person for the purpose of operation or exploration unaided, unless he is a fully-qualified medical man, having sufficient personal acquaintance with the required technique. If two or more practitioners are present at the anæsthesia one must be perfectly experienced in the work, and in that case another may administer the anæsthetic under the responsibility of the first mentioned individual. In hospitals where there is only one medical man another practitioner should be called in for the occasion. The conditions of the anæsthesia must be determined by the responsible individual. Special attention must be paid to the purity of the chemicals used, and an abundant supply of fresh air to the operating room is necessary. A patient must be detained in hospital after anæsthesia at least until all effects of the narcosis have passed away, and on leaving must be accompanied by a person who has been instructed how to take care of the patient in case anything unexpected occurs." In Austria accidents during anæsthesia are very rare. The out-patient departments in particular have hitherto been nearly entirely free from such occurrences. Here the "open-air method" is the one generally preferred, and general anæsthesia is resorted to only when absolutely necessary. The removal of tonsils or adenoids, extraction of teeth, paracentesis of the tympanum, operations on the nasal walls, and other minor operations are performed either without an anæsthetic or under only partial or local anæsthesia. Special care is taken to find out before operation whether the patient is liable to hæmophilia or suffers from the status thymicus. The researches of Dr. Paltauf of Vienna have done much to keep the Vienna surgeons aware of the latter possibility and to cause them to search for it in every case previously to the administration of an anæsthetic.

Historical Researches on Syphilis.

In a recent paper read before the Gesellschaft der Aerzte Dr. Kronfeld gave an account of his researches as to the origin and antiquity of syphilis. The belief is that syphilis made its appearance in Europe in 1493, when the sailors of Columbus returned from the discovery of America, and that the disease then spread like an epidemic over nearly the whole of Europe. Against this hypothesis must be placed the facts that the disease does not now show this pandemic character and that the writings c[illegible] contain passages which seem to [illegible] known in their time. It is certai[illegible] mercury were used in antiquity against certain ulcerative processes of the skin. Dr. Kronfeld has now found a Greek vase dating from the seventh or eighth century B.C., which shows very clearly a dark coloured woman, of negro type, presenting chronic serpiginous ulcerations on her arms and legs, attacked and slain by a Greek woman of unblemished purity of the skin. The ulcers might be due either to leprosy or to syphilis, [illegible] of the figure. [illegible] lesions must l[illegible] covery of America by Columbus. Again, the popular names of the disease in the various European countries exhibit the peculiarity that each nation ascribes the introduction of syphilis within its own area to its enemies. Thus the French call it *mal espagnol, mal anglais, mal indien;* the Spaniards call it *il mal francez;* the Germans also derive it from the French nation; in England "Spanish sickness" was once a familiar term; and the Turks call it "Christian illness." All over the world it is known, and everywhere the same remedies—namely, preparations of mercury, copper, and certain herbs—are used against it. There is no one country to which its origin can be attributed, and no age limit can be positively assigned to it. If vases and other objects of art are examined with this view perhaps more proof will be obtained that in earliest history syphilis was a source of much suffering.

Cerebro-spinal Meningitis in Austria.

The report of the Board of Health dealing with the epidemic of cerebro-spinal meningitis in Austria in 1906–1908 has just been published, and the following facts are worth mentioning. The disease appeared late in 1906 in the north-eastern part of the empire, and soon it was clear that its spread was very difficult to suppress. The cold and wet parts of the country were much more affected than the hot dry parts. The mountainous districts remained nearly immune. The number of cases in 1906 was 1506, with 853 deaths (56 per cent.); in 1907 it fell to 803 cases, with 461 deaths (58 per cent.); and last year it was 504 cases, with 263 deaths (53 per [illegible] there were 2823 notified cases, with 1577 [illegible] decline of the morbidity [illegible] not be brought down [illegible] of the attempts to immunise the "germ carriers" by pyocyanase. The sanguine hopes reposed on the latter substance have not been justified. In spite of repeated sprays and washes of the nose of the "germ carriers" with this liquid, cocci could be shown for weeks afterwards. The results obtained with the meningococcus serum, however, [illegible] proving that the universal adoption of this [illegible] has been urgen[illegible] An intraspinal [illegible] of the serum should be made at once in the lumbar region and if the symptoms do not abate within 24 hours the injection should be repeated. All persons coming in contact with patients should be kept under observation. A search for "germ carriers" and their isolation is the best prophylactic method, as they are the foci of infection more than the patients themselves. The use of the serum has reduced the mortality by 50 per cent., and this year not only is the morbidity very low (170 cases, with 48 deaths, in the empire) up to July 1st, but also the number of fatal cases is much smaller. Observations are going on as to the ultimate fate of those who survive. Already it may be stated that the worst effect of the disease is the loss of hearing, tending to deaf-mutism, as mostly children under ten years were affected, whilst motor disturbances are rare. The cause of the deafness is either panotitis or an inflammation of the labyrinth. Serious mental disturbances have also been noticed, especially in grown-up people, but happily only in very few inst[illegible] fection after an attack may be limited to th[illegible] by the patient; disinfection c[illegible] with as the germs are not able t[illegible] body.

July 26th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Early Diagnosis of Tuberculosis.

THE State Board of Health of Hungary has issued for distribution to the medical practitioners of the country a circular on the early recognition of tuberculosis, giving in a concise and systematic form all the information on the diagnosis of the disease to be obtained from a most exhaustive review of Hungarian and foreign medical literature. The increased attention directed to the prevention and treatment of pulmonary tuberculosis during the last few years has resulted in extensive scientific investigation, and the value of early diagnosis is shown both in prolonging the life of the patient and protecting those with whom he comes in contact. The medical men of the country are also reminded of the laboratories at the university and it is announced that examination of sputum of patients supposed to be tuberculous will be made without cost at any time. "Container stations" for the distribution of postal cases for the conveyance of specimens have been established, and wherever pulmonary tuberculosis is found to be exceptionally prevalent inspectors will be sent to assist in the investigation of the cause, and in taking the necessary steps to check the spread of the disease.

Food Preservatives and Food Adulteration

At the recent meeting of the Royal Society of Medicine partly to the close proximity of the building to the sectional meetings. In this week's issue we commence a detailed account of the more interesting articles exhibited.

Their Excellencies the Earl and Countess of Aberdeen have taken the occasion to show very thoroughly their appreciation of the work of the medical profession by their presence in Belfast during the week and their attendance at many of the functions of the Congress. Besides hearing the President's address they have been present at the opening discussion of the Section of Hygiene and Public Health on the notification of tuberculosis, a disease in the prevention of which their interest is common knowledge, the address in Medicine, the address in Surgery, the address in Midwifery, the annual dinner, and the receptions given by the Lord Mayor and by the members of the Ulster Branch of the Association. On the occasion of the address in Surgery Lady Aberdeen was elected an honorary member of the Association.

On Tuesday evening the large oval Assembly Hall of the Presbyterian Church was occupied by a large audience bright with doctors' robes, assembled to hear the Presidential Address. The presence of the Viceroy and his consort, and of the Lord Mayor of Belfast, gave a full official dignity to the occasion, which was opened by an interesting little ceremony, the investment of Sir William Whitla with the badge of office by Dr. Alexander Dempsey, who hailed the incoming president in words of warm fellowship. Thereon followed the presentation of the distinguished foreign guests and colonial delegates who were received with the customary plaudits, and then Mr. Edmund Owen, chairman of council, took the chair, whilst Sir William Whitla delivered his eloquent address on the History of the Belfast School of Medicine and the need for General Reform in Medical Education. A hearty vote of thanks to the President was proposed by Lord Aberdeen, who spoke in feeling terms of the work of the medical profession and who has been an honorary member of the Association since 1897. This was seconded by Sir Clifford Allbutt, and carried with acclamation.

There was no official church service held this year to inaugurate the meeting of the Association, but on Sunday the cathedral morning service was attended by the President-elect and many members of the Association, before whom the Lord Bishop of Down (the Right Rev. Dr. Crozier) preached an appropriate sermon from the texts, "Luke, the beloved physician," and "Only Luke is with me," in the course of which he commemorated the immortal services to mankind of Simpson, Lister, Jenner, and Pasteur. In the chief Presbyterian church the Rev. Dr. David Purves preached on Religion and Medicine, and uttered a measured warning against the modern intrusion of ministers of religion into the province of the physician.

The Association entertained a distinguished group of foreign guests, who took part in many of the sectional discussions. Professor Bordet of Brussels, who first described hæmolysins and has done so much to advance our conception of immunity, Professor Calmette of the Pasteur Institute of Lille, the inventor of the ophthalmo-tuberculin reaction, and Professor Sanfelice of Naples have contributed papers to, or otherwise assisted at, the Section of Hæmatology; Professor Fehling of Strassburg and Dr. C. Jacobs of Brussels at the Section of Obstetrics and Gynæcology; Professor Sonnenburg of Berlin at the Section of Surgery; Professor E. Fuchs of Vienna at the Section of Ophthalmology; Dr. Delavan of New York at the Section of Laryngology; Professor Richard Greef of Berlin and Dr. Delsaux of Brussels at the Section of Pharmacology; and Dr. Louis Wickham.

The delegates from colonial branches who had signified their intention of being present at the meeting were: Captain E. F. Gordon-Tucker, I.M.S., Bombay; Major N. P. O'G. Lalor, M.B., I.M.S., Burmah; Dr. R. Carter, British Guiana; Dr. H. G. Thomasz, Colombo and Ceylon; Dr. A. W. Dowding and Major H. A. L. Howell, Gibraltar; Dr. J. H. Sanders, Hong-Kong and China; Dr. A. V. M. Anderson, Dr. R. J. Bull, Dr. G. C. M. Mathison, and Dr. G. A. Syme, Melbourne and Victoria; Dr. J. Hyslop and Dr. D. C. Watt, Natal; Dr. W. E. Collins, Dr. A. W. Izard, Dr. J. H. E. Jarvis, Dr. H. J. M'Lean, Dr. C. G. F. Morice, and Dr. W. H. Unwin, New Zealand; Dr. M. Jay and Dr. M. J. Symons, South Australia; Surgeon-General P. H. Benson, South India and Madras; Dr. R. Arthur and Dr. O. Maher, Sydney and New South Wales; Dr. G. Michie, Transvaal; and Dr. Ashton, West Australia.

On Wednesday Professor William Osler, in his capacity of President of the newly formed Medical Library Association, delivered before the packed benches of the chemistry theatre an address on the Medical Library as a Factor in Post-graduate Work, in the course of which he indicated the wealth of medical literature stored in the provincial centres of the United Kingdom, and laid down some admirable rules for the systematic study of books and periodicals by medical practitioners. An interesting exhibit of old medical books was shown by this association during the week. We hope that its President's stimulating address has resulted in a considerable addition to its lists of members.

The housing of all the sections in reception-rooms under the roof of the University has been a great convenience to all concerned. The library has been the scene of the addresses in medicine, surgery, and obstetrics. The local secretaries are to be congratulated on the excellence of their arrangements, and we owe a special acknowledgment to Professor Letts for placing his private room at our disposal to serve as an office during the meeting.

We have also the pleasant duty of thanking the Editor of the *British Medical Journal* and the General Secretary of the British Medical Association for the ready courtesy with which they have placed every facility at our representatives' disposal.

We have no space this week to speak of the many interesting afternoon visits and excursions that were arranged for, and it is hardly necessary to say that wherever the members and guests of the Association were invited they met with the readiest of welcomes from their Irish hosts.

THE SECTIONS.

MEDICINE.

Wednesday, July 28th.

President, Professor **James Alexander Lindsay** (Belfast).

The **President** in his opening remarks gave a brief history of the growth of medical education in Belfast since the year 1820. He also indicated the necessity for the physician to reassert himself owing to the numerous invasions of his department.

Angina Pectoris.

Sir T. **Clifford Allbutt** (Cambridge) in opening the discussion affirmed that angina pectoris deserved in the fullest degree to be regarded as a disease by itself and not merely as a symptom or as a symptom group. After stating that he had been accustomed for some time to divide angina pectoris into angina minor and angina major, he proceeded to consider the symptoms separately. The chief symptom was the pain which arose at or under the manubrium sterni, and not, as is stated in the text-books, copying one another, in the præcordial region. In angina minor it was usually at the manubrium and down the middle third of the sternum. Another symptom was the association of vaso-motor phenomena and the imperious cessation of muscular movements, including even those of respiration. Another important feature was the apprehension of evil which was not necessarily the fear of impending death. The special features in angina minor were that the attack was evoked by muscular effort only, the arterial pressure was usually raised, the condition was nearly as common in women as in men, and there was not usually the fear of impending death. In angina minor the arterial pressure was not necessarily increased. The focus of the disease was so sensitive that even a little increase of pressure would serve to excite it. Angina major was a more terrible condition, but was fortunately less frequent. The pain was at or near the same area; it darted in well-known directions, especially to the arms, usually to the left, sometimes to both, rarely to the right alone. Sometimes it spread to the neck and occasionally it might start in the periphery. In this form the pain was far fiercer and plumbed the very depths of bodily anguish. This form was often fatal. Intermediate cases existed between the two types. Pseudo-angina he dismissed as pseudodiagnosis; it was a functional malady and any reference was out of place in the present discussion. In regard to the vaso-motor phenomena, they were incidents and did not partake of the actual nature of the disease. Sir Clifford Allbutt then proceeded to discuss destructively the various views offered as to the nature of angina pectoris. The first hypothesis regarded the condition as the outcry of a dilated ventricle under stresses, and was now practically abandoned. Dilatation was too common a circumstance to be considered in so uncommon a condition as angina. The second view tried to draw an analogy with intermittent claudication in the legs. This Sir Clifford Allbutt described as a pretty fancy, but he pointed out that in angina the heart does not stumble until it falls once for all. The third view referred the condition to cramp of the heart, but in opposition to this he pointed out that the rhythm was normal. The next hypothesis discussed was that of Sir Lauder Brunton and Dr. Samuel West, which was practically an alliance between two of the preceding views and was in effect that of a crampy dilatation. As opposing this view, Sir Clifford Allbutt maintained that the heart except in fatal cases continued to do its work with [illegible] next view was that of Dr. James [illegible] owing that the heart was intact as regards four of its fundamental qualities, thought it might be deficient in contractility, and regarded the pain as due to cramp of the muscles of the cage of the thorax. Sir Clifford Allbutt held, however, that this cessation of respiration was due to fear and was not a mechanical arrest. The next view was that of Dr. Francis Hare, who suggested the existence of a morbid tension in the mediastinum, which was to some extent an approximation to his own view. The view that the condition was due to inflammation of the cardiac plexus was negatived by the view which Sir Clifford Allbutt asserted, that this plexus was motor in function. The same objection applied to Dr. A. Morison's view which referred the condition to a lesion of the intra-cardiac ganglia. The next explanation discussed was the coronary hypothesis, so strongly advocated by Huchard and Romberg. The objection raised to this explanation was that it did not explain many, and indeed the most typical, of the cases, which did not go to autopsy but recovered completely. Again, coronary atheroma was common in old men, and it was now admitted that coronary embolism afforded no evidence to support this view. Passing from the destructive part of his remarks to the constructive, he propounded a theory, which he first published in part in 1894, but which has not received recognition except by Josué who has fully accepted it. He urged that a condition which not infrequently ended in recovery cannot have its seat in an irreparable damage. His own view was that the origin of angina pectoris was not in the heart but in the suprasigmoid portion of the aorta and its investments. In fatal cases the patient died from vagus inhibition, and death was not due to the lesion itself. This vagus effect might be perceived in attacks which did not end in death. Similar vagal inhibition causing sudden death occurred in operations about the root of the lung, in blows on the testicle, and in gallstone. The fear of death was probably some echo in consciousness of this vagus effect. He believed the suprasigmoid part of the aorta was peculiarly susceptible to changes of blood pressure and that the Pacinian bodies found in its investments were concerned. The morbid summation of stimuli resulting from a drag or pull on the investments of this part of the aorta was transmitted to the corresponding spinal segment or segments and referred to other parts.

In the subsequent discussion Sir LAUDER BRUNTON (London), Professor W. OSLER (Oxford), Dr. W. K. HUNTER, (Glasgow), Dr. W. GORDON (Exeter), and Dr. JOHN HADDON (Hawick) took part.

A paper was read by Dr. D. W. SAMWAYS (Mentone) on Misconceptions Concerning the Riviera, and another by Dr. W. GORDON (Exeter) on the Influence of Soil on Phthisis.

SURGERY.

WEDNESDAY, JULY 28TH.

President, Professor T. SINCLAIR (Belfast).

The PRESIDENT opened the section with a few introductory remarks on the surgery met with in Belfast; there was much casualty practice, as was only natural from the large number of industrial works, and the number of fractures was very great. Aneurysms were very rare, and, as connected with this, he mentioned that syphilis was not very prevalent. Gastric and duodenal ulcers were common, and tuberculosis affecting bones and joints was very frequent indeed.

Mr. B. G. A. MOYNIHAN (Leeds) then opened a discussion on

The Operative Treatment of Obstructive Jaundice and the Proper Selection of Cases.

He commenced by insisting on the extreme difficulty of the subject. With all our present knowledge of the subject, though the diagnosis was generally correct, yet cases occurred from time to time in which the diagnosis turned out to be utterly wrong. There could be no absolute certainty. The most essential point was that sufficient inquiry should be made into the case. There were three branches of inquiry. The first branch was that dealing with the clinical history, and this was the most important of all. The inquiry should specially be directed towards the elucidation of the earliest inaugural symptoms, and by the symptoms the cases of obstructive jaundice fell into two classes. In the first the jaundice was absolutely painless in onset, and it was rarely noticed first by the patient, for it appeared very slowly and deepened day by day, yet, though it came on so slowly, it never receded. Preceding the jaundice and accompanying it there were a general impairment of health and loss of appetite, till at length the patient was emaciated and utterly disliked all forms of food. In the second class of case the onset was nearly always painful, the pain coming first and the jaundice following. The pigmentation increased rapidly, but it was never so deep as in the first form. The tint, too, was different; in the first form it tended to be a deep green, but in the second form it was hardly ever green, but always some form of yellow and brown. The pigmentation ebbed and flowed, and the patient had from time to time attacks of elevation of temperature and attacks of pain. In the former class of case the cause of the obstruction was nearly always malignant disease, perhaps of the head of the pancreas or of the common duct. In the second class the cause was nearly always a stone, but occasionally it was due to the impaction of some other body such as a hydatid. The anamnesis was the most trustworthy of all the means of diagnosis at our disposal. The second branch of inquiry dealt with the physical signs. A well-known law was of great value, and the best form in which it might be stated was that "In cases of obstructive jaundice due to blocking of the common duct contraction of the gall-bladder shows that it is due to a stone." This law holds good in nine cases out of ten; sometimes the presence of two stones may upset it, for there may be a stone in the common duct causing the jaundice, and a second stone in the cystic duct causing distension of the gall-bladder. When ascites is associated with obstructive jaundice it is nearly always due to malignant disease. Mr. Moynihan quoted a case in which a single stone in the cystic duct pressed on both the common bile duct and the portal vein so as to cause jaundice and ascites. The third branch of inquiry is connected with the examination of the urine and fæces, and the researches of Dr. P. J. Cammidge have resulted in methods giving a very substantial help in diagnosis. All the means at the surgeon's disposal should be employed to make the diagnosis as certain as possible. To diminish the tendency to hæmorrhage calcium chloride is quite worthless, and Mr. Moynihan has given it up entirely. He has recently employed the injection of an alien serum, and he finds that it is of distinct service. He considers that it is not desirable to remove the gall-bladder in obstructive jaundice if it can possibly be retained.

Sir **THOMAS MYLES** (Dublin) expressed his agreement with the need of a careful and prolonged examination before operation, for the difficulties of diagnosis could hardly be exaggerated. He had a very small opinion of the law quoted, and he objected to laws being laid down in clinical matters. He had often found it very difficult even to diagnose the existence of a dilated gall-bladder, and the larger it was the more difficult its recognition. It was undesirable to remove the gall-bladder in most cases.

Mr. **E. STANMORE BISHOP** (Manchester) laid stress on the value of Murphy's method in the diagnosis of these cases. He had found calcium chloride useful in preventing hæmorrhage, but he gave it in large doses of 30 grains three times a day by the mouth and from 30 to 50 grains per rectum at the same time. He was much opposed to uniting the gall-bladder to the colon.

Mr. **W. I. DE C. WHEELER** (Dublin) urged the need of diagnosing these cases before the jaundice developed; if obscure symptoms, such as biliousness, were properly investigated the presence of gall-stones would be recognised much earlier. The Cammidge tests were difficult, and there were some simpler tests.

Mr. **C. P. CHILDE** (Southsea) considered that gall-stones should be diagnosed early and should be removed before symptoms develop; the mortality would be much less, for several dangerous results would be avoided.

Mr. **J. CRAWFORD RENTON** (Glasgow) stated that he gave calcium chloride as a routine. He looked forward to the X rays giving valuable information of the presence of gall-stones.

Mr. **A. B. MITCHELL** (Belfast) objected to the employment of an exploratory incision merely for diagnosis. He considered that calcium chloride should be used freely.

Dr. **SONNENBURG** (Berlin) mentioned a case in which jaundice appeared after an ordinary appendicectomy; later coma supervened and the patient died. At the necropsy it was found that acute yellow atrophy of the liver was present.

Mr. **W. McADAM ECCLES** (London) hoped for more help from X rays, which in one case had given a faint indication of malignant disease of the head of the pancreas. In malignant disease causing obstructive jaundice the intense itching may justify draining the gall-bladder. To use calcium chloride effectually it must be given very freely by the rectum.

Mr. **MOYNIHAN** briefly replied.

OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JULY 28TH.

President, Dr. J. CAMPBELL (Belfast).

A discussion on

The Treatment of the Graver Forms of Puerperal Sepsis

was opened by Dr. **THOMAS WILSON** (Birmingham). The following is an abstract of his remarks, which commenced with a statement of the gravity of the disease. Puerperal fever has been made notifiable and there are the strongest possible reasons for provision by the community of effective means for its isolation, study, and treatment, as has already been done in certain other contagious diseases. The absence of such organised provision renders the investigation and study of the disease not only difficult, but incomplete and scrappy, and makes impossible a sufficiently extended practical trial of new and promising methods of treatment. Grave cases of puerperal fever that threaten the life and health of the patient usually arise in the first few days after delivery at term, or less commonly after abortion. At the onset it is impossible to tell whether we are at the beginning of a serious or even fatal illness, or are merely witnessing a mild and passsing toxæmia. So soon as the temperature rises to 102° F. treatment should be begun; delay at this time is the most fatal, as it is the most usual, error. The vulva, vagina, and cervix should be carefully cleansed, a specimen of the contents of the body of the uterus should be obtained for bacteriological examination, and the uterus should be freely irrigated with iodine solution. If this is not followed by marked improvement in the course of 12 hours, or if the temperature again rises, the cavity of the uterus should be explored and any coarse putrescible material removed; for this purpose digital evacuation appears to present solid advantages over the use of the curette; in either case, a copious douche is indicated both before and after the intervention, and an anæsthetic is frequently necessary. In the general treatment of the patient absolute rest in bed is required for a sufficient time; pain may be relieved by applications of heat or cold. Among drugs, the most useful are quinine in large doses; alcohol in moderate quantities carefully regulated and controlled by observations of the pulse, temperature, tongue, and skin; and strychnine in hypodermic injections where there is failure of the circulation. The use of antipyretics is not to be recommended, since fever appears to be a measure of the patient's general resistance. Only in very high fever does the increased temperature itself appear to do harm, and when the thermometer rises above 103° tepid sponging of the surface of the body appears to be useful. With regard to treatment directed against the invading organisms, certain substances appear to have some influence in neutralising the bacterial poisons. It has been claimed by some observers that in colloidal silver or collargol we have a specific for septic infections comparable to quinine in malaria, or mercury and iodide in syphilis. Dr. Wilson had made trial of the drug in a fair number of cases, but has been unable to satisfy himself that it has any definite influence over puerperal sepsis. There have been no ill effects, however, and it appears worthy of extended trial in suitable cases. Subcutaneous injections of normal saline solution and saline enemata are found useful in supporting a failing circulation, and in helping to carry off bacterial poisons and the waste products of the conflict by flushing the tissues. Anti-streptococcic serum has been of little or no use in the treatment of grave cases of puerperal infection. The employment of vaccines made from the organism that has actually invaded the patient's body has been recently recommended, and appears to promise more favourable results. Surgical intervention in various directions and with different objects has been widely employed. Puerperal infection is of infinite variety and imperfectly understood, and cases undergo sudden and unexpected turns, so that prognosis is doubtful and the result of any therapeutic method hard to estimate. In the worst cases the resistance of the body is rapidly overwhelmed and death in a few hours or days inevitable; the expectation of good from treatment of any kind is small. In cases of peritonitis the chance of saving the patient by a timely operation increases in proportion as the symptoms progress more gradually and as larger amounts of fluid collect and become shut off from the peritoneal cavity by adhesions. Large collections of pus should be treated by early and free evacuation and drainage in the most accessible direction. Radical operations on the uterus and its appendages have proved fatal, and should only be practised in certain definite cases, as for instance in sloughing myoma, suppuration in the wall of the uterus, certain cases of rupture, and of septic hour-glass contraction, in suppurating ovarian cysts and ruptured pyosalpinx. In other cases it is desirable to wait if possible for at least six to 12 months until the invading germs have died out or become attenuated, and the natural powers of recovery and repair have had a reasonable chance to complete their work. Where it is not possible to wait it is best to operate through the posterior vaginal fornix, not removing the appendages, but opening up any purulent foci in the appendages or their neighbourhood, and providing for adequate drainage. Hope for the future still centres round prevention, which may be reasonably expected in time to bring about the practical abolition of grave cases of puerperal infection.

In the subsequent discussion,

Professor **J. FEHLING** (Strassburg) said that the chief thing required was a better diagnosis of the different forms of [illegible] that they might change from one form to the other. They had never clearly separated sapræmia from septicæmia; in sapræmia or toxæmia operations were not required. Bacillus coli infection was sometimes a bad one. With reference to treatment, he had come to the conclusion that serum was useless and he had seen no good results from that or collargol. Vaccine therapy might be better, but their experience of it was too short. He had tried injections of 5,000,000 of streptococci in a cubic centimetre, this vaccine being prepared from the patient herself. He did not agree with Dr. Wilson about local investigations and did not examine the interior of the uterus during the first week. He had found good results from douching in infection by coli bacillus or saprophytes, but it was of no use in streptococcic infection, and curetting was dangerous in that condition. He would always open the abdomen in peritonitis and put in a tube, but he did not wash out the cavity. The most important advance in treatment would occur when they could better differentiate the different forms.

Professor **MURDOCH CAMERON** (Glasgow) said that he treated sapræmia in every case by swabbing out the uterus with a mixture of equal parts of camphor and carbolic acid. He did not use the curette.

Dr. **J. MUNRO KERR** (Glasgow) thought that the reason why results were better in hospital than in private practice was because more attention was paid to cleansing the vulva and vagina. As regards treatment of slighter forms, he thought that early exploration of the uterus was undesirable and would not do it unless there was evidence of retained débris or doubt about complete expulsion of placenta or membrane. He was opposed to curettting. In the graver forms he agreed with Professor Fehling that they could not diagnose the real gravity from bacteriological examination but could only decide on clinical grounds.

Dr. **E. HASTINGS TWEEDY** (Dublin) did not agree that sepsis was abolished in lying-in hospitals, and they must depend on morbidity and not entirely on mortality tables. He did not agree that the index of a severe case was a temperature of 102° F. He had known fatal cases with a lower temperature. He pleaded for a more extensive performance of the operation of opening the posterior fornix, followed by a gauze drain; it was a simple operation and could be performed with the patient in bed. Anæsthetics were always badly borne by these patients.

Dr. **HENRY JELLETT** (Dublin) had found that localised abscesses in Douglas's pouch were generally associated with secondary superadded infection by the bacillus coli from the rectum. He asked what were the indications for performing this operation laid down by Dr. Tweedy. Prior advised doing it in every case, but personally he would confine it to cases in which there was a swelling. He made a large opening, washed out with iodine, and plugged firmly with iodoform gauze. He used only the blunt curette.

Dr. **F. EDGE** (Birmingham) drew attention to the danger of introducing further germs into the uterus, in the slighter cases of sepsis, if the vagina and vulva were not disinfected. Before an intra-uterine examination was made; he used only saline for washing out. He advocated that arrangements should be made for the public supply of vaccine.

Dr. **ALFRED SMITH** (Dublin) thought that the diagnosis of thrombosis was extremely difficult. He placed much reliance on the leucocyte count and favoured operation if the latter was low.

Dr. **CUTHBERT LOCKYER** (London) said that his own treatment of the severer forms was to explore the uterine cavity with a gloved hand, and at the same time take a swab for bacteriological examination. He had given up curetting; at [illegible] put in an iodoform [illegible] coccus pyogenes he [illegible] polyvalent serum while a vaccine was prepared; the latter took 48 hours. In coöperation with Dr. Eastes this had been done, and a dose of 2,0[illegible] given but lat[illegible] being [illegible] same time he used intra-uterine douching. He would only open Douglas's pouch when there was a lump present.

Dr. **C. E. PURSLOW** (Birmingham) spoke of the difficulty of providing hospital accommodation for these cases, and thought that provision should be made by the municipalities for the treatment of the poorer cases in the fever hospitals.

Dr. **H. BECKETT-OVERY** (London) quoted the good results obtained by Dr. Knyvett Gordon in the Manchester Fever Hospital.

Dr. **WILSON**, in reply, said that bacteriologists were now confusing us by dividing up the varieties of streptococci, and we were not yet on sure ground as regards the division between hæmolytic and non-hæmolytic forms. As regards the division between slight and severe cases of septicæmia, he took the temperature as being the most convenient guide. He did not think it possible to tell whether the uterus was empty without exploration by the finger, and he would examine if no improvement followed in 12 hours after irrigating.

Dr. **J. J. AUSTIN** (Belfast) read a paper on

Midwifery in Private Practice: a Criticism of Methods based on Results.

465 consecutive cases were referred to. These included 29 abortio[illegible] presentations, one accidental hæmorrhage, [illegible]. There was no ma[illegible], forceps in multiparæ, 26 per cent. in primiparæ, and 8·7 per cent. in all cases. In primiparæ he found that 67 per cent. had perineal tears; these were all sutured at once with silkworm gut.

Dr. **CUTHBERT LOCKYER** then read a paper on the Treatment of Uterine Cancer in the Later Months of Pregnancy.

HYGIENE AND PUBLIC HEALTH.

WEDNESDAY, JULY 28TH.

President, Dr. **LOUIS C. PARKES** (London).

This section opened with a large attendance, which included the Lord Lieutenant of Ireland, the Countess of Aberdeen, and the Lord Mayor of Belfast.

[illegible] said that to [illegible] there was [illegible] urbanisa- [illegible] the towns [illegible] to several serious evils, the chief, perhaps, being the tendency to [illegible] the conditions which were presen[illegible] provements which had been effected by municipal authorities with respect to sewerage, household refuse, water-supplies, and the housing of the working classes. In respect of the air we breathed, towns were still, he said, far behind the country, and as illustrating the conditions under which a large proportion of the factory population worked he referred to the Report of the Departmental Committee of the Home Office on Ventilation, where it was suggested that the standard for CO_2 in the air should be 12 parts per 10,000, involving an air-supply of 750 cubic feet per head per hour, as against the ideal 3000 cubic feet required by de Chaumont. He then referred to the question of the pollution of the air by [illegible] adoption of gas by the working classes [illegible] in-the-slot system, and by the greater recourse to central heating (hot water and steam) for all kinds of large buildings. He pointed out, however, the urgent necessity for having an adequate system of [illegible] when a central method of heating was in use. [illegible] places involved the absence of [illegible] sidered that it was also very [illegible] heat should not be at too high a temperature, otherwise the air became close and stuffy, a condition which was possibly due to minute traces of CO or other incompletely oxidised carbon compounds. In conclusion, he referred to the great work undertaken by the Countess of Aberdeen as President of the Women's National Health Association of Ireland in bringing before the workers and their families the simple rules of health and common sense which are involved in the maintenance of the healthy home.

The Earl of ABERDEEN, in proposing a vote of thanks to the President for his excellent and appropriate address, said that the subject of it would appeal to them all, for they all knew what it was to suffer from the effects of a badly ventilated room. The suggestions made by Dr. Parkes had been practical and of importance. He expressed his thanks for the words of encouragement which had been given to the women workers in the Association in which the Countess had taken so great an interest.

Dr. C. PORTER (Finsbury), as one of the secretaries of the section, read a paper by Dr. Harold Scurfield (Sheffield) on the

Compulsory Notification of all Forms of Tuberculosis.

He said that consumption had been compulsorily notifiable in Sheffield since November, 1903. The administrative procedure which had been adopted as a result included the free bacteriological examination of sputum submitted by medical practitioners in the city; the visitation of notified cases by inspectors who, in addition to giving verbal advice, such as that relating to the opening of windows, leave printed leaflets containing advice and instructions; and the supply of pocket spittoons. When considered necessary disinfection was carried out. Provision had been made by the corporation for the hospital treatment of 20 males and 20 females, who as a rule remained in hospital only for short periods for the purpose of education in the methods best adapted to effect a cure and to prevent the disease spreading to others. A selection was made from those under treatment of those patients who would be benefited by a more prolonged residence in a sanatorium. Patients were also treated in the Sheffield Royal Infirmary. Nearly one-third of the total number of deaths recorded in Sheffield as due to consumption occurred in the workhouse hospitals belonging to the two boards of guardians within whose areas of administration the city of Sheffield was included. In each of these hospitals and in the infirmary modern methods of treatment were adopted. Lastly, there had lately been provided by the education committee an open-air school for delicate children. In his references to the statistical records of tuberculosis, Dr. Scurfield pointed out the necessity for giving separately the death-rates of men, women, and children. The importance of this analysis was emphasised by the fact that in Sheffield, while there was nothing remarkable about the total death-rate of both sexes at all ages, the rate for women alone was very low, and that for men and for children very high.

The Earl of ABERDEEN inquired whether there was any local opposition to the Act before it actually became law and while it was under consideration.

Dr. PORTER stated that as far as he was aware there was no opposition at all, and

The Earl of ABERDEEN congratulated the people of Sheffield upon their enlightenment.

Dr. J. C. MCWALTER (Dublin) said that the results of Dr. Scurfield's paper showed that whereas formerly 11 persons out of every 1000 died from consumption in the workhouse, now 38 persons out of the same number died there, apparently as a result of compulsory notification of phthisis. This was not desirable. It might possibly be necessary to notify in a city like Sheffield, where such a large proportion of the population worked at grinding and cutting of tools and where hundreds of men worked within a few inches of each other, but in cities like Dublin or Belfast, or in rural districts, to register a man as a consumptive branded him as a leper and hurried him into the grave. There were superstitions in science as well as in religion, and the amount of terror of the tubercle bacillus was a twentieth century superstition. First, we were assured that the bacillus would kill us, but when it failed to kill the patient we were told that he had become immune or that the soil was unfavourable. Referring to the passing of the Tuberculosis Prevention (Ireland) Act (1908), he reminded the meeting that an Order in Council had been made under which a medical practitioner was bound to notify to the medical officer of health a case of tuberculosis where the patient habitually slept in the same room with another person not so affected, and he pointed out how difficult it would be to carry out this provision consistently. He strongly disapproved of the notification clauses of the Act. In the very interesting volume published by the Women's National Health Association it was stated, on the authority of the President of the College of Physicians of Ireland, that at least 50 per cent of old men showed signs of tuberculosis. If those cases had been notified, and these men had thus become aware of the disease from which they were suffering, it is probable that they would never have become old men—the fear of the disease and the taint of the leper would have hurried them into the grave. He concluded by arguing that if hospital segregation were complementary to notification the cost would amount to at least £2,000,000 yearly.

Sir CHARLES CAMERON (Dublin) could not agree with Dr. McWalter. Ireland in some respects was far in advance of other countries, notably in the carrying out of the Vaccination Acts. He knew of no instance in Ireland of lack of belief in the efficacy of vaccination, and the Irish people had the greatest respect for all laws which they knew were useful. Ireland was the first country to have a general Act relating to tuberculosis. A terrible disease was in their midst and something had to be done to remedy it, even though that remedy itself were terrible. The inconveniences connected with the carrying out of the Act were trifling when the great object of preventing the disease was considered. The deaths from tuberculosis in Dublin were three times as many as those caused by the principal infectious diseases. The death-rate from zymotic diseases in Dublin 20 years ago was 6 to 7 per 1000 of the population, but the great sanitary improvements which had been effected had reduced that rate to 1·5 per 1000. Those improvements unfortunately had been altogether inoperative in reducing the death-rate from tuberculosis, so that something more must be done. He regretted that the Act was an optional one and was of opinion that if notification were necessary at all it should be compulsory.

Sir JOHN BYERS (Belfast) said that the question of notification must be looked at fairly and straightly if they wanted to bring Ireland into line with England, Wales, and Scotland. They had conditions in Ireland which hardly existed anywhere else, and in order to remedy those conditions they must know first of all where the cases of the disease were, and that could only be secured by means of compulsory notification. Voluntary notification was quite inadequate During six months of 1907 there were notified voluntarily in Belfast 1231 cases of consumption, but during the same period there were 926 deaths, and, assuming that there were about ten times as many cases as deaths, the number of cases which did not come to the knowledge of the health authorities must have been very large. Referring to the statement that Irishmen would not agree to carry out the provisions of the Tuberculosis Act, he reminded the meeting of the very drastic provisions relating to notification which were in force in New York where the population contained a very large number of Irishmen. He hoped that one result of that discussion would be that the Belfast corporation would adopt the Act.

Dr. T. G. NASMYTH (Edinburgh) said that there was a great deal of misapprehension as to the result of enforcing compulsory notification. There was a consensus of medical opinion, as expressed at conferences all over the world, that notification of consumption was a necessary measure. He warned them, however, that other measures were necessary in connexion with notification and as complementary to it.

Dr. A. W. GILCHRIST (Nice) said that the difficulties connected with compulsory notification were hardly realised. He considered that only the "open" cases of tuberculosis should be notified.

Mr. HERBERT JONES (Hereford) pointed out that under the Irish Act only those cases were required to be notified which were of an infectious character, therefore only "open" cases were notifiable. He urged the importance of some steps being taken by voluntary associations to look after the families of men who were suffering from consumption and were thus unable to do so themselves.

Dr. J. L. RENTOUL (Lisburn), speaking as a general practitioner, was altogether in favour of compulsory notification The medical world had done what it could for the consumptive, but now the State must step in and take its share. But the first thing the State must do was to find out who the persons were who required assistance, and this could only be done by means of compulsory notification.

Dr. J. DARLEY WYNNE (Clonmel) referred with some surprise to the fact that hitherto the cattle fairs in Ireland had received no consideration as a possible cause of the spread of tuberculosis in the country. He stated that in many important towns in Ireland the cattle fairs are held in the main streets and not on a market ground. Experiments which had been made by Dr. Shroeder of Washington had shown that about 40 per cent. of cattle apparently healthy, and only known to be tuberculous because they reacted to tuberculin, passed tubercle bacilli in their fæces. The contamination of milk and of other articles of food was thus made possible. He considered that the wide distribution of bovine tuberculosis which must occur when hundreds of cattle were congregated in public streets for hours must be a source of real danger to the community.

Mr. HERBERT JONES read a contribution by Dr. James Niven (Manchester), in which he outlined a scheme for the eradication of tuberculosis among cattle. He suggested that veterinary surgeons of known experience and special skill [illegible] s by a number of county [illegible] by Government, and they [illegible] in made in Government laboratories, the use of tuberculin otherwise than by these officers being under regulation. They would be placed in a definite relationship to the medical officer of health. Their first duty would be to select the farms most suitable for the commencement of eradication, regard being had to the character of the farmer in the first instance and then to the sanitary condition of the homestead. In carrying out the first operation of eradication the cows would be purchased subject to freedom from reaction and under such other conditions as might be deemed necessary Re-acting stock would become the property of the Government and arrangements would therefore have to be made for dealing with them. Necessary measures of disinfection would be carried out by the farmer, the materials being supplied at the public expense. The entire expense of these operations would be borne by the Imperial Exchequer. The stock having been freed from tuberculosis, any subsequent losses from the disease, which ought not to be great, would be borne by the farmer, but a biennial test would continue to be carried out by the veterinary surgeon with tuberculin provided by the Government. All cattle thus [illegible] distinguished [illegible] centres free [illegible] uring the first two or three years to a limited number of farms, but when a sufficiency of stock-producing centres had thus been created a larger number of farms could then be dealt with in the course of the year, the stock on those already dealt with being available for replacement of reacting animals.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 28TH.

President, Fleet-Surgeon J. LLOYD THOMAS, R N.

After an address from the PRESIDENT, a paper communicated by Colonel H. E. R. JAMES, R.A.M.C., on the Medical Branch of the Officers Training Corps, was read, followed by a paper by Lieutenant-Colonel R. PORTER on the Physical Training of Recruits in the Army.

In the discussion that followed the following gentlemen took part: Colonel T. H. HENDLEY, I.M.S., Staff-Surgeon E. COX, R N., and the PRESIDENT.

Colonel HENDLEY then read a paper entitled, "A Contrast Between the Treatment of the Wounded under the Moghul Emperors and King Edward VII., Emperor of India," which was discussed by the PRESIDENT, Lieutenant-Colonel PORTER, and Lieutenant-Colonel E. M. WILSON. After Colonel HENDLEY had replied the section adjourned.

PHARMACOLOGY AND THERAPEUTICS.

WEDNESDAY, JULY 28TH.

President, Professor R. STOCKMAN (Glasgow).

Mr. GEORGE CHIENE (Edinburgh) read a paper on

Spinal Anæsthesia,

which was discussed by Dr. DUDLEY BUXTON (London), Dr. ALEX. DON (Dundee), Professor A. E. BARKER (London), Dr. J. MILL RENTON (Glasgow), Dr. G. A. H. BARTON, Mr. LEEDHAM GREEN (Birmingham), Dr. V. G. L. TIELDEN (Belfast), Dr. W. E. DIXON (Cambridge), and Dr. COFFEY (Egypt).

Professor A. E. BARKER (London) then read

A Short Note upon the Elimination of Stovaine after Spinal Analgesia,

which was discussed by Dr. NEWMAN NEILD (Bristol), Dr. W. E. DIXON (Cambridge), and Dr. H. H. DALE (London).

ANATOMY AND PHYSIOLOGY.

WEDNESDAY, JULY 28TH.

President, Professor C. S. SHERRINGTON (Liverpool)

The PRESIDENT, in his opening remarks, expressed regret at the absence of Professor Symington, and remarked upon the advantages of holding a joint meeting of anatomists and physiologists.

The following papers were read:—

1. On the Anatomy of the Achondroplastic Skeleton, by Professor A. F. DIXON (Dublin). This was discussed by Professor C. J. PATTEN (Sheffield), Dr. D. WATERSTON (Edinburgh), Dr. R. H. SCANES-SPICER (London), Dr. N. C. RUTHERFORD (Edinburgh), Professor PETER THOMPSON (London), and the PRESIDENT.

2. On Some Points in the Mechanics of Respiration, by Dr. R. H. SCANES-SPICER (London), which was discussed by Professor SHERRINGTON, Professor PETER THOMPSON, Dr. J. S. DICKEY (Belfast), Dr. N. C. RUTHERFORD, and Dr. WATERSON.

3. On Phosphatides, by Dr HUGH MACLEAN (Liverpool). This was discussed by Dr. N. C. RUTHERFORD, Dr. REID HUNT (Washington, U.S A.), Professor B. MOORE (Liverpool), and Professor T. H. MILROY (Belfast).

DERMATOLOGY AND ELECTRO-THERAPEUTICS.

WEDNESDAY, JULY 28TH.

President, Dr. W. CALWELL (Belfast)

After an introductory address by the PRESIDENT, Dr. LOUIS WICKHAM, director of the Radium Institute of Paris, gave an interesting lantern demonstration on the Treatment of Skin Diseases by Radium, which was discussed by Sir MALCOLM MORRIS, K.C.V.O. (London), Professor R. B. WILD [illegible] TOMKINSON (Glasgow), Dr. J. H. G. DORE (London), Dr. W. B. C. JAMES METCALFE (Bradford), and Dr. J. A. CODD (Wolverhampton).

After Dr. WICKHAM had replied, Dr. SEQUEIRA communicated a paper by Dr. H. Lewis Jones (London) on the Treatment of Nævus by Radium.

DISEASES OF CHILDREN.

WEDNESDAY, JULY 28TH.

President, Mr. H. J. STYLES (Edinburgh).

The morning was occupied in a discussion on Club-foot, introduced by Mr. ROBERT JONES (Liverpool), and contributed to by Mr. A. H. TUBBY (London), Mr. J. H. NICOLL (Glasgow), Mr. ALEXANDER MACLENNAN (Glasgow), Mr. E. LAMING EVANS (London), Mr. EDMUND OWEN (London), Mr. R. C. DUN (Liverpool), Mr. F. W. COLLINSON (Preston), and the PRESIDENT.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

WEDNESDAY, JULY 28TH.

President, Dr. StCLAIR THOMSON (London).

After some introductory remarks from the PRESIDENT, Dr. J. BARR (Glasgow) read a paper on

The Treatment of Tinnitus Aurium,

confining himself to various non-operative methods of ment. This was discussed by Mr. R. LAKE ([illegible] [illegible] OWLES RENSHAW (Manchester), [illegible] Mr. OLIVER CARLYLE (Edinb[illegible] Mr. W. COUSINS ([illegible]

(Dublin), Mr. LOGAN TURNER (Edinburgh), and Dr. BRYSON DELAVAN (New York).

Dr. HUGH JONES (Liverpool) read a paper on

The Association of Slight Abnormalities of the Auricle, with certain Forms of Deafness,

which was discussed by Dr. G. JACKSON (Plymouth) and Mr. LAKE.

Dr. DAN MCKENZIE (London) read a paper on the Clinical Value of Labyrinthine Nystagmus Tests; and Mr. G. JACKSON on the Etiology of Auditory Meatus Exostosis.

THE ANNUAL EXHIBITION.

THE exhibition of drugs, surgical appliances, special foods, and other matters of medical import seemed to create a greater impression on the visitors this year than has usually been the case. A quite remarkable interest was taken in this important department of the meeting. As early as Tuesday morning (the opening day) the Exhibition Hall in the Botanic Avenue, which is immediately behind Queen's University, was an animated scene of discussion between medical men and the exhibitors, while there was a consensus of opinion that the exhibits had never made a more attractive display. The hall offered the exhibitors a better chance than usual of an advantageous display, for it is a fine and spacious building, very preferable to the drill hall in which so often this big scientific bazaar has been held. The hall was built for the purpose of exhibiting objects demonstrating the application of sanitary science, and the city owes it to the generosity of Dr. Henry O'Neill.

We propose to deal with the various exhibits in the following order: (1) Drugs; (2) Surgical Instruments and Appliances; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Exhibits of a Miscellaneous Character.

I. DRUGS.

Although it is true in regard to this section that there were many familiar products shown, products which recalled something of the kind shown at previous exhibitions, yet on the whole it may be said there were in many instances interesting new departures. It was not surprising to find, in view of certain therapeutic advances, that prominence was given to sera of high potency, to vaccines, and to the new organic arsenic and mercury combinations. Methods of administration by injection and inunction, by the mouth, and so forth, found excellent illustration in a series of most elegant pharmaceutical products. It is a difficult task to point out one set of preparations as being superior to another, where all were aimed at therapeutic efficiency and ease and convenience of administration.

The cases of exhibits shown by Messrs. Burroughs, Wellcome, and Co., of Snow-hill Buildings, London, E.C., were of the highest interest. In addition to their series of fine chemicals, alkaloids, &c., all of ascertained purity and activity, this firm showed their series of organic arsenic preparations, soamin and orsudan; ernutin, containing the active therapeutic principles of ergot physiologically standardised; tyramine, the chief active (basic) constituent of aqueous extracts of ergot and hemisine, a preparation of the active principle of the medulla of the suprarenal gland. They also showed several vaccines, of which the acne bacillus, gonococcus, staphylococcus, and typhoid vaccines are types, and tuberculin for treatment, for diagnosis, and for laboratory tests. Amongst the sera submitted to rigorous tests for sterility and non-toxicity were diphtheria antitoxic serum, anti-colon bacillus serum, anti-dysentery serum, antivenom, and so forth.

Amongst the preparations worth attention and shown at the admirably designed stall of the Hofmann La Roche Chemical Works, Limited, of 7–8, Idol-lane, London, E.C., was that known as digalen, described as an amorphous digitoxin, soluble in water, isolated from the leaves of digitalis purpurea. It is claimed for digalen that it admits of exact dosage, gives a prompt physiological response, has no cumulative effects within the limits of prescribed dosage, and does not cause any gastric trouble. Another preparation of interest at this stall was thiocol, a potassium salt of guaiacol sulphonate, a soluble, tasteless, and odourless substance which has been used in tuberculosis with favourable results, diminishing the number of tubercle bacilli in the sputum, preventing the frequent recurrence of night sweats, and without irritating effects on the gastric membrane. The exhibit included some fine specimens of crystallisation—e.g., caffeine and strychnine, and a preparation known as benzosalin, a benzoyl compound of salicylic acid, which is said to be useful in salicylic acid medication and without the unpleasant side-effects of the ordinary acid and the salicylates. Lastly was shown Secucarnin, a sterile solution of those principles of ergot which are hæmostatic, the nauseating or irritant constituents being entirely eliminated.

There was much to interest the physician at the tastefully arranged stall of Messrs. Parke, Davis, and Co., of 50, Beak-street, Regent-street, London, W. Of perhaps the greatest importance were their preparations containing adrenalin, the constringent and blood-pressure raising principle of the suprarenal gland isolated by Dr. Takamine in 1900, and introduced by this firm to the medical profession. In addition there were a series of bacterial vaccines prepared in the laboratory of St. Mary's Hospital, under the supervision of the director, Sir A. E. Wright; and a number of standardised fluid extracts and mercurettes for mercurial inunction. At this stall from time to time lantern demonstrations were given illustrating the preparation of serums and toxins, the physiological standardisation of drugs, and the manufacture of pharmaceutical products. The Bayer Company, Limited, of 19, St. Dunstan's-hill, London, E.C., showed a very interesting series of fine pharmaceutical products, amongst the latest of which were thyresol, a methyl-ester of santalol, a therapeutic advance on sandal-wood oil in the treatment of gonococcus infection; autan, a self-developing formaldehyde disinfectant; and spirosal, a salicylic oil for external application in rheumatism, to supersede mesotan. The exhibit included, amongst other things, soluble sodium veronal and guaiacose, a 5 per cent. solution of guaiacol-calcium sulphurate in liquid somatose, which has been employed with distinct success in disorders of the respiratory tract.

On Messrs. Oppenheimer and Son's stall, of 129, Queen Victoria-street, London, E.C., were to be seen a number of recent pharmaceutical products. Amongst these were calomel and mercurial "creams" for intra-muscular injection in syphilis, which are said to be painless in action and to cause no local disturbance. There were also shown some sera pulverettes, a pill with a fragile coating which secures the rapid administration of a drug in powdered form; and specimens of "lactigen," a culture of Metchnikoff's bacillus for the preparation of curdled milk. Messrs. Zimmer and Co., Limited, of Frankfort-on-the-Maine, who were represented by Widenmann, Broicher, and Co., of 33, Lime-street, London, E.C., exhibited some interesting compounds, prominent amongst which were euquinine, the now well-known tasteless substitute for quinine which is said to have the same physiological action of that alkaloid but without its objectionable by- or after-effects. The exhibit included allosan, a santalol derivative having advantages in the treatment of gonorrhœa; bromvalidol, a sedative and nerve stimulant; and estoral, a boric acid menthol ester for catarrh of the respiratory organs.

One preparation only, but a good one, was shown on the stall of the Hanley Chemical Manufacturing Company of Hanley, Staffordshire—viz., a liquid hæmoglobin compositus. While containing all the constituents of ox blood it is not at all unpleasant to take. The Angier Chemical Company, Limited, of 32, Snow-hill, London, E.C., exhibited samples of their emulsion of petroleum with hypophosphites. The emulsion is complete, as the microscope shows, and attention is drawn to the remarkable purity of the petroleum employed. "Miol" is the name given to a formula of admitted value in wasting diseases It is a combination prepared by the Miol Company of 82, Southwark Bridge-road, London, S.E., of olive oil, with an active malt diastase, and contains in addition iodine and glycerophosphates. Some novelties were shown by the Huxley's Pharmaceutical Products and Pasteur Vaccine Company of Chichester Rents, Chancery-lane, London. Amongst them were an excellent non-saccharine glycerole of glycerophosphates, and similar preparations but containing formates, hæmoglobin, pepsin, and red bone marrow extract respectively. There were also shown fermentactyl tablets for obtaining sour milk cultures, anti-diphtheric dragées, anti-tetanic serum, and aseptic calf lymph.

The milk of magnesia of the Charles H. Phillips Chemical Company of 14, Henrietta-street, Covent Garden, London, W.C., is, as our own analysis has shown, a pure hydrated oxide of magnesium which serves very favourably as an antacid. The same company exhibited a phospho-muriate of quinine compound, described as a combination of the wheat phosphates with muriate of quinine and strychnia. This is of value as a tonic for the nervous system and digestive organs. Messrs. Woolley, Sons, and Co., Limited, of Manchester, showed a very interesting series of galenical and pharmaceutical products, typifying care and skill in their manufacture. As examples, mention may be made of akolethe, a solution of the sedative principles of opium free from nauseous taste and having no unpleasant after effects; physiologically standardised preparations of ergot, Indian hemp, digitalis, squills and strophanthus, unguentum resorcin co., malto-hæmoglobin, and a series of elixirs of value in disorders of the respiratory tract. They exhibited also an assortment of medical appliances, including trusses, enemas, midwifery outfits, aseptic syringes, and so forth. The chief subject of Messrs. H. and T. Kirby and Co.'s exhibit was purgen, described as the "ideal purgative" which is known to be identical with phenolphthalein, the useful alkali and acid indicator used by chemists in analysis. There can be little doubt of the usefulness of purgen owing to its non-irritating action.

Devoted as well to the exhibition of certain valuable food products, which we hope to describe in a future number, Messrs. Savory and Moore of 143, New Bond-street, London, W., [illegible] chemical food, an excellent preparation of red bone marrow, with iron and calcium glycerophosphates. Messrs. Reynolds and Branson of 13, Briggate, Leeds, succeeded in making their exhibit artistic and attractive by a selection of elegant pharmaceutical preparations, including their concentrated mixtures, bismuth preparations, concentrated tinctures, and opianthe, a preparation of opium containing 0·75 per cent. morphine, and free from nauseous odour and resin.

Liquors, bismuth preparations, heroin compounds, medicinal syrups, and medicated pastilles were praiseworthy features of the exhibit of Messrs. Wyleys, Limited, of Coventry. In addition were some hermetically sealed sterilised glass capsules known as "Wylettes" of actinic proof glass containing 1 cubic centimetre of a sterilised liquid ready for immediate hypodermic injection. The stall of the Maltine Manufacturing Company, Limited, in conjunction with Messrs. Carnrick and Co., Limited, of 24 and 25, Hart-street, Bloomsbury, London, W.C., contained a number of useful preparations in which maltine serves as an effective vehicle. Such are, for example, maltine with hypophosphites, with iron, with pepsin and pancreatin, with creasote, with cascara sagrada, and so on.

Besides a number of excellent apparatus for producing spray (vaporisers, atomisers, insufflators, &c.) in connexion with which his name is so well known, Mr. Frank A. Rogers of 327, Oxford-street, London, W., exhibited some useful medicaments containing heroin; while mention should be made of muscatol, a pleasantly perfumed liquid, proved, it is stated, to be an absolute protection from mosquitoes, gnats, midges, and other insect pests. A veterinary muscatol is also prepared in a concentrated state for the protection of horses, cattle, and dogs from the attacks of similar pests. Messrs. B. Kuhn and Co. of 16, Rood-lane, London, E.C., exhibited samples of the interesting vegetable digestive ferment papain, the exhibit including their pure specimens of ethyl chloride and the antiseptic chinosol. The Saccharin Corporation, Limited, of 165, Queen Victoria-street, London, E.C., showed specimens of novocain, the now well-known local anæsthetic, which is considerably less irritant than other sustitutes for cocaine, while producing an equal degree of anæsthesia. The claims of novocain were set forth fully in a pamphlet on the subject embodying the scientific contributions which have been made from time to time establishing claims in its favour.

II.—SURGICAL INSTRUMENTS AND APPLIANCES.

Compared with previous years this section was not so fully represented. The exhibits relating directly to surgical appliances were quite few in number, although it must be pointed out that considerable interest was shown in the appliances that were presented to view. Perhaps the greatest variety of surgical instruments and accessories was to be found on the two exhibits of Messrs. Down Brothers of 21 and 23, St. Thomas-street, London, S.E., who reserved one stall for the demonstration of aseptic hospital furniture and another for instruments. The exhibit comprised a series of new and original designs which compelled inspection by those desirous of keeping pace with modern appliances.

The stall of Messrs. Siemems Brothers and Co., Limited, of Caxton House, Westminster, London, S.W., displayed X ray outfits and accessories of the latest design, offering the most recent facilities in regard to the application of the [illegible] mention should be made [illegible] h, as its title implies, is designed for the use of the general practitioner. It consists of a 16-inch spark induction coil with 3-part primary winding and spark gauge; a small switch table with ammeter, rheostat with 15 contacts, two three-way switches for the Wehnelt interrupter (which is double and provided with a lead cover and silencer), and a protective screen lined with lead and provided with a lead-glass window, all on castors. When the outfit is used for instantaneous radiography the shunt resistance is cut out and very short exposures can then be obtained by means of the main switch. The exhibit included a larger apparatus with rotating high-tension rectifier for connecting to 220 volt continuous current mains and a universal and safety protective tube-stand. Attention should also be drawn to a series of radium and radio-active substances and radioactive earth for local application and for baths. Messrs. C. A. Hoefftcke, Limited, of 21, Woodstock-street, London, W., exhibited their well-known appliances for joint diseases, for fractures, a corset for lateral curvature, and Openshaw's appliance for obtaining extension of the spine in the treatment of scoliosis and caries or injuries to the spine. The exhibits included the auto-gloving machine, the distinct merits of which have already been discussed in our columns.

Messrs. Meyer and Meltzer of 71, Great Portland-street, London, W., presented examples of recent surgical instruments which are described in their new catalogue on "General Surgery." A feature was made of their "University" examination lamps for the general surgeon, the ophthalmologist, the laryngologist, the aurist, the gynæcologist, and so on. Close by Messrs. Fannin and Co., Limited, of Dublin, had a quite interesting assortment of up-to-date surgical instruments, including anæsthetic appliances, midwifery outfits, electro-medical appliances, urine-test cases, orthopædic appliances, and so forth. The Lee antiseptic air producer (S. Lee, 51, Conduit-street, London, W.) attracted considerable attention. This apparatus produces a warm powerful current of antiseptic air in a continuous volume at a velocity of 250 feet per minute, which may be used for inhalation. The apparatus has many advantages in the treatment of the lungs and throat with antiseptics, and its action is similar to that of the Bunsen burner. The Liverpool Lint Company, of Mark-street Mills, Netherfield-road North, Liverpool, showed an interesting assortment of surgical dressings, absorbent gauze tissue, surgeons' tow, carbolised tow, and "vulnoplast," a new surgical antiseptic dressing with a self-adhesive edge, requiring no other attachment to dress a wound. A local firm, Messrs. John Clarke and Co., Limited, of 8, Donegal-square West, Belfast, had a very neatly arranged [illegible] instruments, bandages (Irish linen [illegible] &c. At the stall of [illegible] London, E.C., a very effective and simple apparatus for producing chloride of ammonium smoke was shown.

The excellent exhibit of Messrs. John Weiss and Son, Limited (287, Oxford-street, London, W.), of surgical instruments attracted the notice due to a careful assortment of appliances of the most recent model. The exhibit included a selection of ophthalmic instruments, Landolt's armamentarium, retinoscopes, and so on. A very complete exhibit of surgical instruments was also shown by the Holborn Surgical Instrument Company, Limited, of Holborn-circus, London, E.C., a feature of it being the Holborn £25 prize set of instruments for surgeons commencing to practise. Practically the only illustration on any scale of treatment by radiant heat and light was given by the Dowsing Radiant Heat Company, Limited, of 24, Budge-row, Cannon street, London, E.C, while Messrs. Hearson, Limited, of 235, Regent-street, London, W., shared the distinction of alone exhibiting biological incubators. Here, also, were autoclaves, centrifuges for hand or mechanical power, Hearson's patent opsonic incubator for the determination of opsonic index, and a biological incubator for researches in embryology and histology.

Messrs. Gale and Sons, Ltd., of Dominion Works, Birmingham, and Whitfield Bedsteads, Limited, of Watery-lane, Birmingham, exhibited a series of beds for hospital and asylum use known as the "Lawson Tait" spring bedsteads, the exhibit including also some excellent examples of aseptic hospital furniture. Mr. G. H. Zeal, of 82, Turnmill-street, London, E.C., presented for inspection a considerable number of his "Repello" clinical thermometers, which obviate the shaking down of the mercury column in order to reset it by means of a depressible bulb. He exhibited also an aseptic germ-proof clinical thermometer. There were, lastly, several appliances of medical and surgical interest shown at the stall of Messrs. Reynolds and Branson, Limited, of 13, Briggate, Leeds, including some special retractor and dissector forceps, towel clips, apparatus for testing urine, ophthalmic lamp, first-aid case, and many other apparatus calculated to assist materially the general practitioner.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination held on July 19th, 20th, 22nd, and 23rd the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—[illegible] University College; Wilfrid Andrew, King [illegible] thur Batchelor, St. Mary's Hospital; Mal [illegible] Hospital; Samuel Caplan, St. Mary's Hospital; Francis Howard Cleveland, St. Bartholomew's Hospital; George Malcolm Coope, Manchester University; David Lloyd Davies, University College, Cardiff; Ralph Marsh de Mowbray, St. Thomas's Hospital; Edmund Rupert Dermer, Middlesex Hospital; Carl Keating Graeme Dick, and Sidney Ernest Elphick, St. Mar [illegible], London Hospital; John Wesley Gilbert [illegible] ol; Evan Williams Griffith, University [illegible] Gwynne-Jones, London Hospital; Jan [illegible] ng Cross Hospital; Charles Lyon Herkl [illegible] College; Rupert Bannatyne Hick, St. Mary's Hospital; Frank Edwin Johnson, Plymouth Technical School; Richard Bertram Johnson, University College, Bristol; Frank Winter Lawson, Brighton Municipal College of Science; William Douglas McDonald, Birkbeck College; Robert Charles Matson, Guy's Hospital; Claude Jocelyn Delabere M [illegible] istol; John Meredydd Parry, University [illegible] Victor Percy Pill, St. Mary's Hospit [illegible] yn, Guy's Hospital; John Thomas Sam [illegible] John Patrick Shaw, Middlesex Hospital [illegible] St. Mary's Hospital; Frederick Lionel Spalding, Guy's Hospital; John Masfen Stack, Birmingham University; William Allan Stewart, London Hospital; Gavin Stiell, St. Thomas's Hospital; Thomas Harold Thomas, London Hospital; Cedric Norman Vaisey, University College, Bristol; Philip Pennefather Warren, London Hospital; Thomas Mansergh Wood-Robinson, Portsmouth Municipal College; and Pelham Vansittart Wynn-Werninck, University College, Bristol.

Physics.—George Aspinall-Stivala, St. Bartholomew's Hospital; Hugh Woodward Barnes, King's College; Cyril Armond Bernard, Liverpool [illegible] Charles Oakley Brown, Birmingham Uni- [illegible] ord Cresswell, Middlesex Hospital; [illegible], University College, Bristol; Arthur [illegible] Thomas's Hospital; William Reginald [illegible] Hospital; Alfred Morgan Hughes, [illegible] iversity; Joseph [illegible] Alwyne Harold [illegible] Prichard, Uni- [illegible] Gerald Robinson, Manchester University; [illegible] Smith, Charing Cross Hospital, Walter Bernard Risk Stower, St. Bartholomew's Hospital; Frank Sykes, Leeds University; Arthur Geoffrey Turner, St. Bartholomew's Hospital; Oscar Ramsay Unger, University College; Algernon Randolph Upton, St. Bartholomew's Hospital; George William Watson, Leeds University; and Kim Glen Wee, St. Thomas's Hospital.

Chemistry.—Albert John Drew, Guy's Hospital; Edward Hugh Morris, Charing Cross Hospital; John Casper Munch, London Hospital; William John O'Kan [illegible] Chisman Pitman, Hartley Colle [illegible] Plant, Manchester University; [illegible] Hospital; Charles Pearse Crod [illegible] Hospital; Evelyn Alexander Sutton, Charing Cross Hospital; Henry John Hugh Symons, King's College; and George Harvey Duder Webb, University College.

Biology.—Alexander William Charles Bennett, St. Thomas's Hospital; William McHutchison Binning, University College; Samuel Caplan, St. Mary's Hospital; Paulin Roger Chevreau, Guy's Hospital; William Lonsdale Cockcroft, Manchester University; David Lloyd Davies, University College, Cardiff; John Edgar Davies, Guy's Hospital; Ralph Marsh de Mowbray, St. Thomas's Hospital; Charles Theodore James Drobig, St. Mary's Hospital; Aylmer Green, City of London College; James George Hanahn, Charing Cross Hospital; Charles Lyon Herklots, B.A. Oxon., University College; Alfred Morgan Hughes, Birkbeck College; Frank Edwin Johnson, Plymouth Technical School; Harold Dunmore Lane, London Hospital; Frank Winter Lawson, Brighton Municipal College of Science; Alwyne Harold Manfield, London Hospital; Robert Charles Matson, Alan Vivian [illegible] Stanley Morgan, Guy's Hospital; Edward H [illegible] ross Hospital; Arthur Rennie [illegible] Kenneth Montague Nelson [illegible] William John O'Kane, Middlesex Hospit [illegible] rtridge, Guy's Hospital; Hugh Ley Puxon [illegible] llege; William Reginald Pryn and Pierre [illegible] Rathier du Vergé, Guy's Hospital; Cecil [illegible] Mary's Hospital; Archibald Frank Salsbu [illegible] John Thomas Samuel and Vincent Russell Smith, St. Mary's Hospital; Frederick Lionel Spalding, Guy's Hospital; John Masfen Stack, Birmingham University; George Sydney Stathers, Cambridge University and St. Mary's Hospital; Gavin Stiell, St. Thomas's Hospital; Ramon Romero SyQuia, London Hospital; Cedric Norman Vaisey, University College, Bristol; and Vernon Charles Whitby Vickers, St. Mary's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. A. [illegible] Cambridge and London Hospital; W. J. M [illegible] rdeen; and H. M. Pollard (Sections I. and [illegible]

Medicine.—J. M. Burke (Section I.), Middlesex Hospital; A. H. C. Dawes (Section II.), [illegible] J. A. Jones (Section I), Manchester; W. J. [illegible] and Aberdeen; H. M. Pollard (Sections I. [illegible] Hospital; and J. W. Williams (Section I.), Guy's Hospital.

Forensic Medicine.—H. V. Humphry, Westminster Hospital; W. J. Morton, Edinburgh and Aberdeen; and H. M. Pollard, Royal Free Hospital.

Midwifery.—W. H. Hooton, Leeds; E. B. Keen, Charing Cross Hospital; G. Moyer, University of Graz; W. J. Morton, Edinburgh and Aberdeen; J. K. Nariman, Bombay; and H. M. Pollard, Royal Free Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: H. A. Hancock, W. J. Morton, and H. M. Pollard.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

M.D. EXAMINATION FOR INTERNAL AND EXTERNAL STUDENTS.

Branch I., Medicine.—Edwin Lancelot Ash, B.S., St. Mary's Hospital; Ernest Frederick Finch, B.S. and Thomas Mellor Hardy, B.S., University of Sheffield; Pantland Hick, B.S., University of Liverpool; Arthur John Scott Pinchin, B.S. (University medal), St Thomas's Hospital; and Edwin Joseph Wyler, B.S., London Hospital.

Branch III., Mental Diseases and Psychology.—Henry De Vine, B.S. (University [illegible], Bristol.

Branch IV., [illegible] *of Women.*—Eustace James Carey Dick [illegible] St. Mary's Hospital; Philip William H [illegible] and Dorothea Clara Maude, B.S., Marian Mayfield, B.S., Eleanor W. Perkins, B.S., Mary Flint Taylor, B.S., Ida Clare Tengely, B.S., and Edith Louisa Young, B.S., London (Royal Free Hospital) [illegible] Women

Branch V., State Medicine.—Dora [illegible] London (Royal Free Hospital) Sch [illegible] University College; Henry Joseph [illegible] Hospital and King's College; Cec [illegible] Cross Hospital and University Colle [illegible] B.S., St. Mary's Hospital.

Branch VI., Tropical Medicine.—James Connor Maxwell Bailey, St. Bartholomew's Hospital; and Frederick Fenn Elwes and Ivor Davenport Jones, Middlesex Hospital and London School of Tropical Medicine.

M.S. EXAMINATION FOR INTERNAL AND EXTERNAL STUDENTS

Seymour Gilbert Barling, University of Birmingham; Vincent Zachary Cope, B.A., M.D., St. Mary's Hospital; and Albert James Walton, B.Sc., London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF LIVERPOOL.—The following degrees were conferred at the graduation ceremony on July 10th:—

Ch.M. (*Ex-officio*).—W. Thelwall Thomas and Robert Jones.

M.D.—J. A. Murray Bligh, H. E. Heapy, H. R. Hurter, L. Hutchinson, A. Hendry, T. W. Jones, S. J. M'Clellan, J. E. W. MacFall, and J. Graham Martin.

M.B., Ch.B.—W. A. Daley (first-class honours), K. J. C. Bradshaw (second-class honours), A. G. W. Owen (second class honours), N. W. Steinberg (second-class honours), and J. W. Cropper.

At examinations held recently the following were successful:—

FIRST M.B., CH.B. EXAMINATION.

Parts I. and II.—C. W. Dixon, J. R. Jones, E. B. Marsh, A. C. Mooney, H. S. Pemberton, R. E. Roberts, and J. St. G. Wilson.

Part II.—F. A. Belam, A. D. Bigland, H. E. Marsden, R. Martlew, and Beatrix M. Walker.

SECOND M.B., CH.B. EXAMINATION.

Part A.—D. H. Clarke, R. C. Crooke, J. E. Getting, R. Heald, N. P. Laing, J. London, and G. W. Mooney.

Part B.—R. W. Gemmell and M. T. Morgan.

FINAL M.B., CH.B. EXAMINATION.

Part I.—J. Bamforth, J. E. Barnes, J. Campbell, A. A. Dear, E. S. Miller, W. R. Wade, and T. W. Wadsworth.

Part II.—K. J. C. Bradshaw, J. W. Cropper, W. A. Daley, A. G. W. Owen, and N. W. Steinberg.

Final B.D.S. Examination.—F. Halsall.

First L.D.S. Examination.—P. G. Capon, C. Q Dinn, S. S. Tiflin, and W. Williams.

Second L.D.S. Examination.—J. Burns, W. B. G. Jones, and J. Tyson.

Final L.D.S. Examination.—G. F. P. Clapham.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

Degree of M D. by Examination.—J. O. Smyth.

Degree of Ch.M.—H. Archibald Smith.

[illegible]

Second M.B. and Ch.B. Examination.—G. S. Bate and G. E. Sawdon. Anatomy: Harold Harrison, D. S. Jones, and H. O. Wright.

Third M.B. and Ch.B [illegible] Anatomy: P. S. G [illegible]

[illegible] mpson, James Walker, [illegible] Warner, and Gordon Whitehead. [illegible] K. D Bean, Rupert Briercliffe, [illegible] A. W. Gaye, P. S. Green, Harold [illegible] Howlett, R. C. Hutchinson, R. A. [illegible] Lapage, W. H. Laslett, Jane [illegible] Howarth Parkinson, W. Hoyle [illegible] B. Scott, W. A. Sneath, William [illegible] G. K Thompson, James Walker, [illegible] Warner, and Gordon Whitehead.

Diploma in Public Health.—Andrew Baxter, Frank Butterfield, R J. Chapman, J. A. Fairer, D. P. M. Farquharson, C. C. Finlator, Alexander Grant, Henry Herd, Harriet McCloghrey, Annie Mooney, Sheila M. Ross, Elsie M. Royle, Barnett Saul, H. G. Ward, and Henry Whitehead.

Sanitary Inspectors Certificate Examination—J. H. Colley, Harold Howard, H. M. Jackson, S. Smith, and Lilian Watson.

Final B.D S.—O. R. Allison.

Diploma in Dentistry, Final Examination.—J. O'H. Kennedy.

Diploma in Dentistry, Third Examination.—C. E. McNabb.

UNIVERSITY OF DURHAM.—At the Convocation held on July 24th the following degrees and diploma were conferred:—

Doctor of Medicine.—Vincent Edgar Badcock, Charles William Mènelaus Hope, Elizabeth Niel Niel, and Howard Bewlay Stephenson.

D [illegible] *n Years' Standing.*— [illegible] ohnson Hildige, John [illegible] oseph Adam Nolan, [illegible] nest Ringrose, John [illegible]

B [illegible] *of Surgery (B S.)*— [illegible] n George Campbell, M.A., Harold Alexander Cooper, Patrick Albert Galpin, Francis [illegible] upon-Tyne

Degree of Bachelor of Hygiene (B.Hy.)—Sydney Havelock, Howard Bewlay Stephenson, and Thomas Leathard Wormald.

Diploma in Public Health (D.P.H.).—Sydney Havelock, William Tait Sewell, Howard Bewlay Stephenson, Frank Thomas Herbert Wood, and Thomas Leathard Wormald

At the Third Examination for the degree of Bachelor of Medicine the following candidates satisfied the examiners:—

P [illegible] *and Elementary* [illegible] amilton Barclay, [illegible] *Honours (Second* [illegible]

[illegible]

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students have successfully passed the examination held at the end of the thirtieth session, April to July:—

*P. Bahr, *P. J. de Miranda, *J. A. Harley (Colonial Service), *R. Brooke (Captain, U.S. Army), *R. A. Lloyd (Captain, I.M S.), C H. Bowle-Evans (Major, I.M.S.), W. E. Giblin, J. L Lunham (Captain, I.M S.), T. Chalmers, W. H. Peacock (Colonial Service), [illegible]

In all, 51 students have taken out the course. The accommodation at the *school provides for only 40 students in* [illegible] out five in each of the special [illegible] t classes the school has been [illegible] the generosity of a friend of the school, the laboratories will be enlarged during the long vacation, and it is hoped that when the school reopens in October there will be sufficient accommodation for all who desire to go through the curriculum even if they are more numerous than in the present session.

UNIVERSITY OF EDINBURGH.—The following degrees in medicine and surgery were conferred at the graduation ceremonial of the University of Edinburgh on July 23rd:—

Doctor of Medicine—‡James Allen Ainscow, Alford William Anderson, Marion Hamilton Archibald, Breadalbane Blacklock, Walter James Buchanan, ‡Claude Ernest Addison Coldicutt, [illegible]

* Awarded Gold Medals for their theses.
† Highly commended for their theses
‡ Commended for their theses.

Master of Surgery—William Maxwell Munby and David Percival Dalbreck Wilkie (awarded gold medal for thesis).

Bachelor of Medicine and Bachelor of Surgery.—Fergus Armstrong, Alice Elizabeth May Babington, Thomas Henry Balfour, Thomas Chalmers Borthwick, Ajit Mohan Bose, William Gillon Brand, [illegible] Gavin Stiell Brown, †Alexander [illegible] Harry [illegible] arbara [illegible] ackay, [illegible] ander [illegible] MacQueen, Andrew Jam [illegible]

M'Kay Reid, †John Renwick, †D [illegible] rtson, William Stewart Robertson, Dermi [illegible] Ross, Richard Picton Rosser, Charles [illegible] James M'Intosh Shaw, Kerr Simpson, Gec [illegible] Henry Faithful Smith, George Smith Sc [illegible] illiam Stewart, Cyril Patrick [illegible] van, Arthur Loudoun Taylor, Henry [illegible] Thompson, Wyville Smyth Thoms [illegible] e Whetter, John Wilson, *John Dykes Wilson, and Margaret Chapel Young.

* Passed with First-class Honours.
† Passed with Second-class Honours.

Diploma in Tropical Medicine and Hygiene.—Ethelbert William Dyer and Joseph Robinson.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred on July 21st:—

Degree of M.D.—†Williamina Abel, M.B., Ch.B.; *T. C. Boyd, M.A., M.B., Ch.B.; E. K. Mackenzie, M.B., Ch.B.; and *C. J. R. Milne, M.B., C.M., I.M.S. (under Old Regulations).

* Commendation for Thesis. † Honours for Thesis.

Degree of M.B., Ch.B.—G. S. Melvin (second class honours), W. J. Allan, W. J. Calder, M.A., R. W. Chalmers, W. Chapman, D. Craig, R. G. Davidson, H. Duguid, R. W. Eddie, A. M. Geddes, W. I. Gerrard, Elizabeth McHardy, G. Macpherson, J. Rae, M.A., G. E. Shand, W. L. Stephen, F. W. Stuart, J. E. Thompson, and R. Tindall.

John Murray Medal and Scholarship (awarded to the most distinguished Graduate (M.B.) of 1909).—G. S. Melvin.

The Diploma in Public Health was also conferred on—

J. Laing, M.A., M.B., Ch.B. Aberd.; J. A. Milne, M.B., Ch.B. Aberd.; and J. A. Watt, M.B., Ch.B. Aberd.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. N. H. Swellengretel has been recognised as *privat-docent* of the Morphology of the Protozoa.—*Baltimore (Johns Hopkins University):* Dr. Clemens von Pirquet of Vienna has been appointed Professor of Pædiatry.—*Berlin:* Dr. P. Fraenckel has been recognised as *privat-docent* of State Medicine, Dr. Katzenstein as *privat-docent* of Laryngology and Otology, and Dr. Forster, Assistant in the Clinic for Mental and Nervous Diseases, as *privat-docent* of Psychiatry and Neurology.—*Breslau:* Dr. Robert Scheller of Königsberg has been appointed to the charge of the Department of Hygiene in the University Institute in succession to Professor Reichenbach.—*Freiburg:* Dr. Oscar de la Camp has been appointed Professor of Medicine in succession to Dr. Bäumler, retired.—*Gottingen:* Dr. Heinrich Vogt, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Gratz:* Dr. Walter Schauenstein has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Greifswald:* Dr. Richard Stern of Breslau has been appointed Extraordinary Professor of Clinical Medicine in succession to Dr. Minkowsky.—*Kiel:* Dr. Hoppe Seyler has been promoted to an Honorary Professorship.—*Marburg:* Dr. Edward Müller of Breslau has been appointed Extraordinary Professor of Medicine.—*Munich:* Dr. Bernhard Heine of Königsberg has been appointed Professor of Otology.—*New York (College of Physicians and Surgeons):* Dr. R. Burton-Opitz has been appointed Professor of Physiology in succession to Dr. John G. Curtis, resigned.—*Prague (German University):* Dr. Gallp has been offered the post of Professor of Anatomy.—*Prague (Bohemian University):* Dr. Josif Znojemsky has been recognised as *privat-docent* of Surgery.—*Rio de Janeiro:* Dr. Aloysio de Castro has been appointed Professor of Medical Pathology in succession to Dr. Miguel Pareira.—*Rome:* Dr. Umberto Deganello has been recognised as *privat-docent* of Medical Pathology.—*Tubingen:* Dr. Max Brunn, *privat-docent* of Surgery, has been granted the title of Extraordinary Professor.—*Turin:* Dr. Francesco Anellani of Pavia has been recognised as *privat-docent* of Neurology.—*Utrecht:* Dr. van Leeuwen has been recognised as *privat-docent* of Pathological Anatomy.—*Vienna:* Dr. Nikolaus von Jagie has been recognised as *privat-docent* of Medicine.

LEICESTER INFIRMARY.—At a meeting of the house committee held on July 28th the following resolution was moved by Sir Edward Wood (chairman of the board), seconded by Mr. B. W. Russell, and carried unanimously:—

[illegible] of the infirmary. The house com- [illegible] ir deep gratitude and great appreciation not only of this present handsome gift but of former generous contributions respectively to the extension fund amounting in all to £3000, and of Messrs. N. Corah and Sons' continued interest in the work, of the infirmary:

PRESENTATION TO A MEDICAL PRACTITIONER.—At Carmel Methodist Chapel, Abercrave, Swansea Valley, recently, Mr. T. E. Richards, M.B., Ch.B. Edin., J.P., medical officer of health to the Ystradgynlais district council, was presented with an illuminated address, diamond scarf-pin, and gold chain. Mrs. Richards was also made the recipient of a diamond ring, a pair of silver candelabra, and a case of cutlery. The presentation was organised to signalise Dr. Richards's appointment to the commission of the peace for the county of Brecon.

THE QUEEN ALEXANDRA SANATORIUM, DAVOS.—The prospective opening of the sanatorium for the reception of patients early in this autumn was announced from the chair at the sixth annual meeting of the council, held at 11, Chandos-street, Cavendish-square, W., on July 16th, by the President, the Lord Balfour of Burleigh, who has laboured so long and so successfully in the difficult task of raising funds. The magnificent donation of £25,000 just received from a munificent sympathiser, who desires that his name shall not be published, not only supplies the necessary balance to complete the work and to open the sanatorium free from debt, but provides the means for its scientific equipment and for future extensions. For the present the sanatorium will accommodate 54 patients, all in single rooms. But the public rooms are devised for a full complement of 120 patients. The Davos Invalid's Home, the original foundation of the late Mrs. Lord, which for so many years was the only representative of our national charity in Davos, has now ended its task and fulfilled the purpose for which it was initiated—namely, that of developing into a national sanatorium. The home had been granted Royal patronage as far back as 1899.

THE KING AT THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—The new in-patient department of the Royal National Orthopædic Hospital was opened by the King on July 23rd. His Majesty, who was accompanied by the Queen and Princess Victoria, was received at the entrance, where a guard of honour of the Honourable Artillery Company were drawn up, by the Duke of Marlborough (the president of the hospital), Lord Denbigh (the chairman), Lady Denbigh, the Mayor and Mayoress of Marylebone, Sir R. B. Martin, and Sir Samuel Scott (the treasurer). Subsequently an address was read to Their Majesties, in which it was stated that the committee of King Edward VII. Hospital Fund for London, having realised that great economies of management might be effected by a policy of amalgamation among those special hospitals carrying on similar work in London, had urged the committees of the old Royal, National, and City Orthopædic Hospitals to amalgamate their funds and build a central institution. That building, which provided for 200 in-patients, most of whom were children suffering from malformations which could be cured in the early stages, was the first realisation of the policy of concentration. In addition to the hospital itself they had a nurses' home and an out-patients' department, where last year more than 11,000 cases were treated. The cost of the buildings had amounted to about £75,000, of which £20,000 were still required. More than 400 patients were now waiting for admission. The King, in his reply, said he was sure that there was no lack of generosity among those who were able to contribute to the support of such an institution, and that the pressing needs of the hospital merely required to be brought home to the imagination of those who would be glad to give did they but realise the urgent necessity for help. Lord Denbigh then made a number of presentations to the King, and the ceremony concluded.

LONDON COUNTY COUNCIL.—At its meeting on July 27th the London County Council adjourned until after the recess the consideration of the Asylums Committee's recommendation that two receiving houses for the early treatment of the insane should be established in the metropolis (see THE LANCET, July 24th, p. 249). When the matter comes up again Mr. Hayes Fisher has given notice to move on behalf of the Finance Committee that only one receiving house be established.—At the same meeting the Public Health Committee submitted to the Council a proposal (announced in THE LANCET of July 17th, p. 199) that Parliamentary powers should be sought to enable sanitary authorities in the metropolis [illegible] of stables and to control the sal[illegible] committee's recommendation, [illegible] able opposition, and on a divi[illegible] not forthcoming to enable the matter to be proceeded with Mr. Simmons, who moved the reference back, did not object to the inspection of [illegible] ought that the growth of motor [illegible] of the horse" made legislation [illegible] Mr. Whitaker Thompson, who seconded, had such a dread of officialism that he hinted uncleanliness might be preferable. Mr. Gilbert Johnstone, chairman of the committee, urged that if the premises of large cartage contractors and cab proprietors were more cleanly, the fly nuisance, which in his experience was worse in the East End of London than in Egypt, would be much abated. It might also be possible to stamp out glanders, in dealing with which the Council spent thousands of pounds annually. Mr. Johnstone mentioned that nine of the metropolitan borough councils wished to have powers to inspect costermongers' barrows. At present shopkeepers were subject to constant inspection, but street vendors escaped scot free. Mr. Johnstone's arguments, however, failed to win over a sufficiently large majority of the Council. Less than two-thirds voted in favour, and the proposal fell through.

TWO NOTABLE RUSSIAN LIBRARIES —The *Torg. Prom. Gazeta* prints a message from Novotcherkask saying that the Donsk Polytechnic is about to acquire the Mendeleieff Library, for which purpose the institution is endeavouring to raise 12,000 roubles The *Novoe Vremya* states that the Pirogoff Library has acquired the library of Professor Polotebnoff, who died last year. It consists of some 400 volumes on dermatology and other branches of medical science, and it was so well known in Europe that the professor's widow received offers from Leipsic and Dresden for the collection, which includes the learned professor's own works on dermatology. But she preferred to make a gift of the collection to a Russian institution.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Departmental Committee on Coroners

THE first report of the Departmental Committee appointed to inquire into the law relating to coroners and coroners' inquests and into the practice in coroners' courts has been presented to Parliament

The Local Education Authorities (Medical Treatment) Bill.

The Local Education Authorities (Medical Treatment) Bill has passed through all its stages in the House of Commons. When it came up for consideration on report a new clause was added in the following terms "Nothing in this Act shall be construed as imposing any obligation on a parent to submit his child to medical inspection or treatment under section thirteen of the Education (Administrative Provisions) Act, 1907." The Bill was afterwards read a third time

Milk and Dairies (Scotland) Bill

Some alterations have been introduced into the text of the Milk and Dairies (Scotland) Bill by the House of Lords The committee stage was completed at one sitting on July 22nd The Bill, by Clause 5, required that all dairies should be licensed annually by the local authority Lord BALFOUR of BURLEIGH took exception to the trouble involved to the dairyman in taking out an annual licence, and put forward a proposal to institute a register of dairies When once a dairy was on this register it was not to be removed except for a sufficient reason Amendments carrying out this proposal were inserted in the clause against the desire of the Secretary for Scotland At the instance of Lord PENTLAND Clause 9 was recast. By it, as it now stands, a local authority which finds that milk is being brought into its area from a district where the provisions of the Bill are not properly observed must first complain to the local authority of that district before applying to the Local Government Board to intervene Several other changes with regard to details were introduced into the Bill

Nurses' Registration.

Delegates from organisations in favour of the registration of nurses had a meeting at the House of Commons on July 26th Their object of meeting was to consider the terms of a Bill which might prove acceptable to all the organisations, and as such would be introduced next session It is understood that obstacles were encountered in the consideration of the details of the Bill, and no decision was made with regard to them.

The Health of the Troops in India

A motion of Sir WILLIAM COLLINS has been passed by the House of Commons for a return showing the cases of, and deaths from, enteric fever, cholera, plague, and small pox (with corresponding rates per 1000) in the native army and among European troops in India respectively, for each year from 1900 to 1908 inclusive

HOUSE OF COMMONS.

WEDNESDAY, JULY 21ST.

The Inspection of Diseased Meat.

Mr WATT asked the President of the Local Government Board what countries in Europe besides Great Britain had their meat inspection now done by their medical officers of health, and whether, in view of the public danger if unsound imported meat was not detected, he would see that all inspectors appointed in the future had attended a course of lectures on meat inspection and had taken a certificate thereon —Mr. BURNS answered The information at my disposal does not enable me to answer the first part of the question precisely, but I may point out that other European countries do not, as a rule, have a service of local medical officers whose administrative functions correspond with those of medical officers of health in regard to the inspection of food. I have no reason to believe that the port medical officers of health cannot satisfactorily perform the duty of judging whether meat is unsound. It is, however, the practice of the Local Government Board before sanctioning the appointment, under the Foreign Meat Regulations, of inspectors or other persons to act under the direction of the medical officer of health in relation to the powers and duties imposed on him by the regulations, to require evidence that these persons are qualified to perform them

Mr W. THORNE: In the event of meat being condemned has the right honourable gentleman any guarantee that it is destroyed?

Mr BURNS: Yes, it is destroyed in every case Unsound meat is invariably sent to the destructor and a certificate is given of its destruction

Mr W. THORNE: What occurs in the many cases where there is no destructor?

Mr. BURNS The unsound meat is destroyed in other ways—in furnaces or by means of chemicals.

The Manufacture of Morphine in India.

Mr. LAIDLAW asked the Under Secretary of State for India whether the Indian Government had established or contemplated the establishment of a factory for the manufacture of morphine.—The MASTER of ELIBANK replied Opium alkaloids in small quantities are extracted in the Government opium factories from waste opium, but the Indian Government has not established and does not contemplate establishing a factory for the manufacture of morphine

Indian Medical Practitioners

Mr KETTLE asked the Under Secretary of State for India whether he was aware that there were highly qualified and experienced Indian medical practitioners who were not allowed to work even as honorary surgeons and physicians on the staff of Government hospitals, and whether any steps would be taken to put an end to the existing system, which was detrimental to the interests of all concerned —The MASTER of ELIBANK wrote in reply: The number of surgeons and physicians who can be attached, in whatever capacity, to Government hospitals is necessarily limited As to the policy of the Secretary of State and the Government of India in regard to medical appointments generally, I would refer the honourable Member to the papers recently presented to Parliament

Mr KETTLE also asked whether the chief medical advisers to the Government of India and to the local governments were to be military officers of the Indian Medical Service, whether the appointment of civil medical practitioners to important posts would depend on the recommendation of these officers, and whether he was aware of the general belief amongst Indians that there could be no real reform so long as the chief posts were reserved for military medical men —The MASTER of ELIBANK replied The Secretary of State is not at present in a position to add anything to his answer to the honourable Member's question of June 17th last as to the manner in which the policy recently laid down can be carried into effect

Mr. KETTLE further asked whether the honourable gentleman was aware that some London Schools of Medicine were practically closed to Indian students, and whether he would take steps to see that persons qualified from such schools were not employed by the Government of India in its medical service —The MASTER of ELIBANK answered: The Secretary of State does not think it advisable to modify the existing arrangement under which the medical services of the Government of India are open to the profession generally

Steevens' Hospital

Mr HAZLETON [illegible] Ireland what acti[illegible] ensure that in fu[illegible] diseases such as [illegible] allocated to the c[illegible] other occupants of the ward —Mr. BIRRELL furnished the following reply: I am informed by the constabulary authorities that there has always been a separate ward in the hospital for ordinary infectious disease. A special ward has now been set apart for pulmonary tuberculosis.

THURSDAY, JULY 22ND.

Hospital Accommodation and the Royal Irish Constabulary.

Mr. HAZLETON asked the Chief Secretary to the Lord Lieutenant of Ireland whether members of the Dublin Metropolitan Police Force were permitted by their authorities, in case of illness, to select their own hospitals; whether this practice had been found to be prejudicial to the public service; whether he was aware that the Royal Irish Constabulary object to be sent compulsorily for treatment to Steevens' Hospital; and whether, in view of the fact that faith was a large factor towards recovery, especially in serious illness, orders would be issued giving the Royal Irish Constabulary a choice in the selection of hospitals.—Mr. BIRRELL replied: In case of illness the men of the Dublin Metropolitan Police are generally allowed to select the hospital to which they wish to be sent, and this practice has not been found to be prejudicial to the public service. I am not aware that the Royal Irish Constabulary object to be sent compulsorily to Steevens' Hospital, and the constabulary authorities see no reason for changing the existing practice which has worked well and harmoniously for many years.

Medical Inspection of Elementary Schools.

Mr. SUMMERBELL asked the President of the Board of Education to state the number of medical officers for elementary schools that had made reports to his department; when the Board's promised medical report on such inspection would be ready; and whether such report would indicate the reforms, if any, recommended by such medical officers.—Mr. RUNCIMAN replied: Reports have been received from 253 local education authorities. These reports will be dealt with generally in the Board's report, which will, I hope, be ready for issue in October.

Lunacy in Ireland.

Mr. VINCENT KENNEDY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had seen in the last annual report of the inspectors of asylums in Ireland that the increase of lunacy in that country since 1880 was 10,949; had the increase for the last few years been continuous; would he say what the population of Ireland was in 1880, and the then number of lunatics, and also the population of Ireland for 1908 with the number of lunatics; could he say whether there was a similar increase, per head of the population, of this disease in any portion of the British dominions; and had the present Government considered [illegible] be done to cope with the increase of this almo[illegible] Mr. BIRRELL (by written answer) replied: I [illegible] referred to. I am informed by the inspectors of lunatics that in 1880, when the population was estimated at 5,202,648, the number of lunatics under care in Ireland was 12,982, and that in 1908, when the estimated population was 4,371,436, the number of lunatics under care was 23,931, an increase of 10,949. The increase has been continuous, but has tended somewhat to fall off in recent years. In England the increase in the registered insane between 1880 and 1907 was 52,971. In Scotland the increase between 1880 and 1908 was 8185. The Government has had before it a report dealing at length with the causes which, in the opinion of the inspectors, have contributed to swell the numbers of insane in institutions in Ireland. This report was presented to Parliament in 1906 (Cd. 3126).

The Metropolitan Asylums Board and Vaccination.

Mr. B. S. STRAUS asked the President of the Local Government Board whether he was aware that the hospital committee of the Metropolitan Asylums Board had made it a condition of tenancy of cottages on their property that every person residing therein should be vaccinated and revaccinated to the satisfaction of the medical officer; and whether such requirement had been sanctioned by the Asylums Board and by the Local Government Board.—Mr. BURNS furnished the following written reply: As regards the cottages on the small-pox hospitals estate of the [illegible] Green, Dartford, it has been made [illegible]son residing in them shall satisfy [illegible] [illegible]nall-pox hospitals that he or she is adequately protected against small-pox or shall consent to be vaccinated or revaccinated. The condition has been laid down by the hospitals committee of the managers, acting in their behalf, and in pursuance of the general policy agreed to by the managers and the Dartford sanitary authorities, and approved by the Local Government Board, for the protection of the neighbourhood of the small pox hospitals against the disease. It only applies to the cottages on this particular estate.

The Queen Alexandra Imperial Military Nursing Service.

Mr. BOULTON asked the Secretary of State for War why colonial training in large general hospitals was not accepted for the Queen Alexandra Imperial Military Nursing Service.—Mr. HALDANE wrote in reply: My honourable friend has been somewhat misinformed. Colonial training is accepted under the same conditions as training at home. It depends, however, on the opinion of the nursing board whether any particular nurse-training institute attached to a hospital is accepted for recognition

TUESDAY, JULY 27TH.

The By-laws of the Royal College of Surgeons.

Dr. V. H. RUTHERFORD asked the Secretary of State for the Home Department whether, in view of the attitude of the members of the Royal College of Surgeons, as shown in the memorial recently submitted, he proposed to sanction the new by-laws proposed by the Council of the Royal College of Surgeons.—Mr. GLADSTONE answered: The matter is still under my consideration.

Public Health in Croydon.

Mr. W. THORNE asked the President of the Local Government Board whether he was aware that, according to the report of the medical officer of health of the borough of Croydon for 1908, numerous cesspools in the Croydon rural district were in direct communication with water-bearing strata from which drinking-water was derived; that the local authorities did not attempt to put into operation the model building by-laws of the Local Government Board, which insisted on builders [illegible]king cesspools watertight; that cesspools in the district were allowed [illegible]uilt in defiance of the by-laws and in such a way as to encourage the direct flow of sewage under 20 or 30 feet of pressure into porous chalk; and that within the Croydon drainage areas there were in 1907, according to the borough engineer's report, 249 houses drained by cesspools which were capable of being connected with the sewers; was he aware that the medical officer had urged the necessity of safeguarding and extending the present water-supply; and, seeing that in January, 1908, the Croydon corporation laid the facts before the Local Government Board, would he say what action the Board had taken, or proposed to take, in the matter, and what assistance or advice the Board could give on the whole question of water-supply from the chalk.—Mr. BURNS replied: I am aware of the reports of the medical officer of health and borough engineer referred to in the question. I communicated with the rural district council and was informed that it had succeeded in persuading a considerable proportion of the owners concerned to connect their premises with the public sewers. I advised them as to the powers which they possessed for dealing with cases when such connexions had not been made, and I subsequently issued an order conferring upon them certain additional powers under the Public Health Acts Amendment Act, 1907. Further, I am causing some scientific investigations to be made with regard to chemical means of purifying chalk waters. I am fully alive to the importance of the subject.

The Inspection of Imported Meat.

Mr. WATT asked the President of the Local Government Board whether, in the regulations under the Public Health (Regulations as to Food) Act, it was the Customs officer whose duty it was to call in the medical officer of health to examine imported meat which the Customs officer considered unsound; if so, would he say whether that official was qualified by training to decide what meat was diseased and what meat was wholesome; and, if not, would he alter the regulations so that all meats imported were subjected to expert examination.—Mr. BURNS replied: It is the case that an officer of Customs would not be qualified by training to decide what meat is diseased and what meat is wholesome, but the regulations do not require him to do this. His duties under them are to require that certain classes of foreign meat, whether it is diseased or not, shall not be removed until they have been examined by the medical officer of health, and that other classes of foreign meat shall not be removed if by reason of facts brought to his knowledge or of representations made to him, he is of opinion that the meat requires examination by the medical officer of health. The responsibility for expert examination rests with the medical officer of health, and he may examine any foreign meat whilst it is still in the district, although it has not been detained by the officer of Customs It does not appear to me that any alteration of the regulations is necessary.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOOTH, S. H., M.B., B.S. Lond., has been appointed House Surgeon at the General Infirmary, Leeds.

BRUCE, JOHN MITCHELL, M.D., F.R.C.P. Lond., has been appointed to the Consulting Staff of King Edward VII. Sanatorium at Midhurst.

BUDD, ARTHUR, M.B., B.S. Durh., has been appointed Medical Officer of Health of Launceston (Cornwall).

BUXTON, DUDLEY W., M.D., B.S. Lond., M.R.C.P. Lond., has been appointed Lecturer to the newly created Lectureship in Anæsthetics at the Royal Dental Hospital of London.

CHALMERS, T. A., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Harris District of the county of Inverness.

DALLY, J. F. HALLS, M.D. Cantab., M.R.C.P. Lond., has been appointed Physician to the St. Marylebone General Dispensary, Welbeck-street, W.

DAWSON, B., M.D., F.R.C.P. Lond., has been appointed to the Consulting Staff of King Edward VII. Sanatorium at Midhurst.

FLINT, H. L, M.B., Ch.B. Leeds, has been appointed House Physician at the General Infirmary, Leeds.

HACKNEY, C., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Hythe District of the county of Kent.

HALLOWES, K. R. C., M.B., B.Ch. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bellanagh District of the county of Cavan.

HUNT, ERNEST, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Kingsteignton District by the Newton Abbot (Devon) Board of Guardians.

KEYSER, CHARLES R., F.R.C.S. Eng., has been appointed Surgeon to the Cancer Hospital, London.

MACK, E. G., M.B., B.S. Lond., has been appointed House Surgeon at University College Hospital.

MOLE, HAROLD FREDERICK, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Bristol Royal Infirmary.

OLDFIELD, CARLTON, M.D., B.S., M.R.C.P. Lond., has been appointed Honorary Surgeon to the Hospital for Women and Children, Leeds.

SAVAGE, WILLIAM GEORGE, B.Sc., M.D. Lond., L.R.C.P., M.R.C.S., D.P.H., has been appointed Medical Officer of Health for the County of Somerset, and Medical Officer of Schools to the Somerset County Council.

SCOTT, SYDNEY, M.S. Lond., F.R.C.S. Eng., has been appointed Surgeon for Diseases of the Ear and Throat at the National Hospital for the Relief and Cure of the Paralysed and Epileptic, Queen-square.

SINCLAIR, HAROLD WEIGHTMAN, M.D. Lond., L.R.C.P. Lond., M.R.C.S., D.P.H. Lond., has been appointed School Medical Inspector by the Gloucestershire Education Committee.

SMITH, GEORGE MUNRO, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Consulting Surgeon to the Bristol Royal Infirmary.

SPEARMAN, R., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Clacton-on-Sea District of the county of Essex.

THOMSON, H. A., M.D., F.R.C.S. Edin., has been appointed Professor of Surgery in the University of Edinburgh.

WALTERS, CHARLES FERRIER, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Surgeon to the Bristol Royal Infirmary.

WOODSEND, R. N., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at University College Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM UNIVERSITY.—Lecturer on Pathology and Bacteriology.

BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BURNLEY, VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing.

CARSHALTON, SURREY, CHILDREN'S INFIRMARY.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.

CHELTENHAM GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board and lodging. Also Surgeon-in-Charge of the Branch Dispensary, unmarried. Salary £80 per annum, with board and lodging.

CHESHIRE, CROSSLEY SANATORIUM, Delamere Forest.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry.

CHESTER GENERAL INFIRMARY.—House Physician. Salary £90 per annum, with residence and maintenance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Clinical Assistant.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon. Salary at rate of £60 per annum, with board, residence, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 per annum, with board, apartments, and laundry.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum.

GERMAN HOSPITAL, Dalston, N.E.—Honorary Anæsthetist.

HARRIS PARISH.—Medical Officer. Salary £126, with house.

JERUSALEM, BRITISH OPHTHALMIC HOSPITAL.—Assistant Ophthalmic Surgeon. Salary £300 per annum, with house.

LANCASTER, ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEEDS UNION, IN-DOOR INSTITUTIONS, Beckett-street.—Assistant Medical Officer. Salary £120 per annum, with board, washing, apartments and attendance.

LIVERPOOL INFIRMARY FOR CHILDREN.—House Surgeon for six months. Salary £30, with board and lodging.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER, ANCOATS HOSPITAL.—Resident House Physician. Salary £80 per annum, with board, residence, &c.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer, also Assistant Resident Medical Officer. Salary in each case £50 per annum, with board and residence.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—Assistant House Surgeon. Salary £75 per annum, with board, &c.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, with all found. Also Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 per annum, with all found.

SALFORD UNION INFIRMARY.—Senior Assistant Resident Medical Officer. Salary £150 per annum, with apartments and attendance, without rations.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £100 per annum, with apartments, rations, &c.

SHOREDITCH INFIRMARY, Hoxton-street, N.—Second Assistant Medical Officer. Salary £100 per annum, with rations, washing, and apartments.

SUNDERLAND INFIRMARY.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

SUNDERLAND, MONKWEARMOUTH AND SOUTHWICK HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

WALLINGFORD, BERKS COUNTY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, attendance, &c.

WIGAN INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with rations and apartments.

THE Chief Inspector of Fa [illegible] ster; at Tralee, in [illegible] in the county of [illegible]

THE Secretary of State for the Home Department gives notice of a vacancy under the Workmen's Compensation Act, 1906, for the Sheriffdom of Stirling, Dumbarton, and Clackmannan.

Births, Marriages, and Deaths.

BIRTHS.

BOKENHAM.—On July 26th, at Highview, Wokingham, Berks, the wife of Thomas Brandon Bokenham, M.R.C.S., L.R.C.P., L.S.A., of a daughter.

MILLIGAN.—On July 26th, at Upper Brook-street, W., the wife of W. Anstruther Milligan, M.D., of a son.

MARRIAGES.

BAS[illegible]

WHITE—TICHENER.—On the 22nd inst., at St. George's, Hanover-square, by the Rev. David Anderson, Rector of the parish, Charles Francis Orr White, M.R.C.S., L.R.C.P., son of the late John Orr White and Mrs. Orr White of Sunnyside, Norwood, to Edith Nina, younger daughter of Mr. Edward Tichener of Heath View, Walton, Epsom.

DEATHS.

PHILLIPPS.—On July 27th, at Savoy Mansions, W.C., Alfred Phillipps, M.R.C.S., aged 68.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

accurate method will be by having bacteriological examination of the lochial discharge," or "offensive lochia"; or "the rise of temperature above 100·5°F., persisting for more than 48 hours, should be regarded as indicative of infection, unless it can be clearly demonstrated to be due to some other cause. If the rule were adopted that all such cases should have a leucocyte count, uterine cultures and blood cultures, a positive result might clearly determine which febrile cases are septic"; while, in opposition to such a rigorous criterion, some said in reply to the question, "Have you any suggestions as to general adoption of a standard for use in maternity hospitals to serve as an index of septic morbidity?" "No. Every one who is fit to be in charge of a lying-in hospital is capable of deciding this, and a standard is, in my opinion, useless," and another reply to the same query was "No. The diagnosis of septic morbidity is usually easy enough to the unprejudiced observer." The majority of the maternities, however, regarded pulse, and especially temperature, as the best and most easily available evidence of puerperal morbidity. In a paper, a Plea for the Early Recognition and Treatment of Puerperal Fever, published in THE LANCET of August 22nd, 1896, I pointed out that the early symptoms of puerperal infection were elevation of temperature and quickness of pulse; and, while I mentioned certain intercurrent non-septic conditions which might raise the pulse and temperature after delivery (giving, at the same time, the diagnosis between them and cases of puerperal infection), I wrote: "I think, then, if we exclude conditions such as I have mentioned, and which, after all, are not very common, we are warranted in concluding that it is, on the whole, rare to have fever and quick pulse in the first five or six days after labour from any other cause than infection." The Committee on Puerperal Morbidity appointed by this Association made the following recommendations:—

1. That irregularities in temperature occurring during the 24 hours following delivery should not be considered for statistical purposes.
2. That as the time puerperal patients remain in hospital varies in different institutions, statistical tables should be formed from the records up to the end of the eighth day after delivery.
3. That statistical records should relate only to patients delivered after the sixth lunar month of pregnancy. (It is recommended that cases delivered before the end of the sixth lunar month of pregnancy should be tabulated separately.)
4. That records of pulse and temperature should be taken twice a day in every case, the following precautions being observed:—
   (a) The temperature to be taken night and morning; if possible, between the hours of 7 and 9 A.M. for the morning, and between the hours of 4 and 7 P.M for the evening record.
   (b) The temperature to be taken in the mouth.
   (c) The thermometer to be kept in the mouth for four minutes.
5. That the title of puerperal morbidity should include all fatal cases, and also all cases in which the temperature reaches 100° F. on any two of the bidaily readings from the end of the first to the end of the eighth day after delivery.
6. That all cases which according to this convention are "morbid" should be tabulated in statistics, the probable cause of the illness and its duration in days being given.

This may be called the British Medical Association standard. On the other hand, at the Rotunda Hospital, in deciding what is the morbid indication, a more certain criterion in the Master's opinion is adopted, and regard is had both to pulse and temperature. If a patient's temperature and pulse, taken twice daily, rise above 99° F. and 90 respectively on three consecutive occasions, counting from the beginning of the second day to noon on the eighth (the time normal cases are discharged), she is regarded as being morbid. Abortion cases are included, but patients dying without fever are excluded. If a patient's pulse and temperature exceed these limits she is not allowed to leave the hospital until they fall to normal for three consecutive takings, and should a patient be retained in hospital after the eighth day and then show any morbidity she is reckoned in the morbidity statistics. Temperature and pulse must together rise above these limits and remain above them for three consecutive bi-daily takings, or, to put it another way, for 24 hours, before a case is regarded as morbid, the temperature being always taken in the mouth. In this way transitory and unimportant elevations of pulse and temperature (to which it would be unfair to apply the term "morbid") are excluded, and, further, the irregularities of pulse and temperature often met with in the 24 hours after delivery are also excluded. Now, with the exception of certain transitory nervous influences and the presence of intercurrent maladies wholly independent of the puerperal state, in the great majority of cases as defined in this way by the Rotunda standard of morbidity, the cause is infection by micro-organisms or by the toxins of retained lochia. So far back as 1891, in a paper on Puerperal Fever, its Nature, Prevention, and Treatment,[4] I used these words: "The experience I have gained at the clinic in diseases of women at the Royal Hospital and in private practice has brought prominently before my attention the fact that many of the chronic ailments of women are traceable to some feverish attack which sets in after parturition." Subsequent knowledge, acquired in the Belfast Maternity Hospital and in the gynæcological ward of the new Royal Victoria Hospital, has shown me that a large number of those affections of an inflammatory nature, to which we give the term "pelvic inflammatory disease" in women, are cases of puerperal infection which, when they occur in a maternity institution, cause its "morbidity," and which, with a more complete aseptic and antiseptic technique, will in time be banished from lying-in hospitals as well as from private practice. These are the cases of child-bed illness which so often ruin health, which cause an immense amount of invalidity and chronic suffering, and which, it is estimated, constitute at least one-third of hospital gynæcological patients. When I studied at the Rotunda Hospital no clinical thermometers were in use; it was in the year 1882 that they were first introduced, and, as pointed out by Dr. E. Hastings Tweedy,[5] the notebook of the assistant master of that period, which I have inspected, shows that of 99 cases in which the temperature was taken, in no less than 50 per cent. there was morbidity, nine had temperatures of 105° F., and 18 temperatures of 103° F., yet the Master reported the condition of the hospital of that date as having been "particularly healthy."

Now, let me contrast the year 1884 (when the British Medical Association met last in Belfast) with the present time as regards mortality and morbidity in two Irish maternity hospitals. In the year 1883–84, from Nov. 1st to Oct. 31st (Arthur Macan, Master), 1109 patients were confined in the Rotunda Hospital with nine deaths, and of these 1109 there were 281 in whom the temperature was over 100·4° F. and the percentage of morbidity was 25·34. In the last year of which we have records, from Nov. 1st, 1907, to Oct. 31st, 1908 (E. Hastings Tweedy, Master), 2060 patients were confined in the Rotunda Hospital with only seven deaths, and in only 126 was the temperature over 100·4° F.—that is, a percentage morbidity of 6·12. Of the seven deaths, only three were due to infection (one was admitted infected, another had been examined outside, and the third was a case of incomplete abortion with a fœtid discharge on entering hospital). It will be seen that, with nearly double the number of patients, there is less than half the number of actual morbidities, and also fewer deaths. As the present Master of the Rotunda points out in a letter to me, these results are better than the figures actually show, because—

1. Many patients formerly left the hospital on the fifth day, an occurrence now almost unknown.
2. The old thermometers did not register under six minutes, and, as a result, they were often taken out too soon. Further, they were placed in the axillæ and not in the mouth, as at present—a method which gives a much more accurate record.
3. The present nurses at the Rotunda are much better educated than those of bygone days; they live in the house and are more thoroughly supervised, and, as a consequence, more reliable observations are made.

It is very interesting to note how the "morbidity" is gradually falling in the Rotunda, as shown by the following table. The estimate is made according to the Rotunda method:—

Years.	Morbidity.
1903–04	10·70 per cent.
1904–05	6 67 ,,
1905–06	4·33 ,,
1906–07	3 99 ,,
1907–08	3 64 ,,

In former years in Belfast there were so-called epidemics of puerperal fever in our maternity hospital, necessitating its being closed on several occasions, and numerous cases which would now be classified as examples of "morbidity." At present such a state of affairs is unknown, and in our new, much-enlarged hospital, where both students and pupil midwives are trained, we had during 1907 and 1908 12 deaths out of 1355 deliveries, and of these only four deaths were due to puerperal infection. (In one the patient had been in labour for 24 hours, attended by an unqualified woman before admission; another, with a contracted pelvis, had been in labour several days before admission; and in a third, the child was born in an *advanced state of decomposition.*) Further, in 1908 our cases of morbidity from every cause, estimated on the standard that the occurrence of one temperature of 100·4° F. indicated a pathological condition, were 9·42 per cent., which is distinctly lower than at Hofmeier's well-known clinic. Again, owing to the aseptic and antiseptic management of the mother during her confinement, as well as by the adoption of special prophylaxis in the care of the child, cases of ophthalmia neonatorum in both maternities are now extremely rare.

---

[4] Dublin Journal of Medical Science, May–June, 1891.
[5] Rotunda Practical Midwifery, p. 36.

These statistics show the present condition of obstetric medicine as practised in two Irish maternities—the Rotunda in Dublin, the largest midwifery institution in the British Empire, and in the Maternity Hospital, Belfast, in both of which students and midwives receive practical training. How have such splendid results been brought about in getting rid of that terrible scourge so often termed puerperal fever and in reducing the number of cases of morbidity? Simply by the careful and thorough carrying out of a series of details evolved step by step in the great campaign against infective microbes.

1. By recognising, as was so well taught by the great Viennese obstetrician, Boer[6] (who really acquired the knowledge largely when visiting France and this country), that, in at least 75 per cent. of the cases, labour is a natural process not needing interference, and that its tendency is to prevent infection, and that our duty is to follow and aid it, and to interfere only when the resources of nature fail to protect the interests of mother or child The uncalled-for use of the forceps, early *rupture of the membranes, douching*—unless under very special circumstances—and the improper management of the third stage of labour are things of the past in properly conducted maternities.

2. By the thorough application of the most minute surgical cleanliness as regards patient, nurse, and doctor during labour and the puerperium.

3. By the adoption of Credé's teaching, enunciated so far back as 1886, when he wrote, "Even the simplest manipulation may cause infection. It should, therefore, be laid down *and taught as a fundamental principle that internal examination* of parturient women should be altogether avoided or restricted within the narrowest possible limits. It can be *very well replaced by external examination.* To instruct their pupils as thoroughly as possible in this method is the present and future duty of teaching institutions."

4. By the immediate suture of any laceration occurring during the process of labour.

In my opinion, the most scrupulous surgical cleanliness in all manipulations, the thorough sterilising of every article coming in contact with the patient, the greatest possible employment of the external methods of examination, and the strict limitation of internal examinations to cases in which the external plans have failed to give the necessary information, combined with the use of rubber gloves (recollecting, however, that sterile fingers, even when covered with recently boiled rubber gloves, may carry in infective bacteria unless the utmost care is taken to prevent contact with the inner surface of the labia and borders of the hymen), despite F. Ahlfeld's views,[7] these are the most important elements in the technique of a modern maternity hospital for the prevention of septic mortality and morbidity.

Professor Hofmeier,[8] estimating the puerperal morbidity on the basis that any case which shows even for once a temperature of 100·4° F. must be regarded as pathological, has recently pointed out that the percentage of morbidity at the Würzburg clinic was 11·48 per cent., while Scanzoni found that out of a series of 157 precipitate births, of 97 women who were never touched vaginally by any examining finger at all 21·6 per cent. had a rise of temperature of between 102° and 104° F.; while of 112 parturients who were confined without any contact from without, 11·5 per cent. had a rise of temperature up to 102·5° F., which it is presumed arose from infection. From such facts the conclusion might naturally be drawn that, do what we will, the woman who is confined can infect herself. But, on the other hand, it may be said that some of these supposed examples of auto-infection may *have arisen from external sources after delivery, during the* puerperium, as it was in this way that the morbidity of 10·7 in 1903–04 at the Rotunda had its origin in great part after the birth of the children. No doubt a very small porportion of septic cases may, during the lying-in period, seem to be examples of auto-infection. I have seen a case where in a primipara a rise of temperature was proved to be owing to the infection of the uterus with the pneumococcus, and, what was still more curious, the baby suffered from a broncho-pneumonia. In another case a lady was infected from a septic phlebitis of the veins of the vulva which were inflamed before her confinement. The Master of the Rotunda has had similar cases, but that such so-called cases of "auto-infection" must be very few in number is clearly proved by the fact that the more thorough and complete is our aseptic technique the less is the morbidity. Further, the very remarkable gradual fall from year to year in the number of the morbidity cases at the Rotunda—as shown in the statistics I have quoted—is totally against the view that auto-infection is anything but a rarity in well-conducted maternities. It is a remarkable fact that puerperal infection (mortality or morbidity) is very uncommon among savage people, or among the patients confined on their way to a maternity; its risk seems to increase with the amount of interference, for in a maternity the morbidity is always less in those normally delivered than in those requiring assistance—a fact which shows how necessary it is, even in such institutions, to strive to improve the aseptic technique in operative cases.

The following statistics showing the mortality in England, Scotland, and Ireland, kindly supplied me by the Registrar-Generals of these countries, indicate that the puerperal infection is still a cause of many deaths—a fact all the more remarkable in face of the results in maternities, and when one considers how typhus fever, small-pox, enteric fever, and (outside Ireland) tuberculosis have all declined so markedly during the past quarter of a century:—

Deaths from Puerperal Sepsis.

ENGLAND AND WALES.

Year.	Numbers.	Death-rate to 1,000,000 females living.
1901	2079	122
1902	2003	118
1903	1668	97
1904	1654	94
1905	1734	98
1906	1640	93
1907	1465	81

In England and Wales the numbers were for the year 1884 2580, being a death rate of 186 per 1,000,000 females living.

SCOTLAND

—	1904	1905	1906
Puerperal septicæmia, sapræmia ...	113	124	123
Puerperal pyæmia	2	5	10
Puerperal fever (not otherwise defined)*	126	119	130
Total	241	248	263

* Including puerperal fever, puerperal peritonitis, puerperal perimetritis, puerperal endometritis, puerperal phlebitis, &c.

The statistics for 1907 are not yet available. In 1884 the deaths from "puerperal fever" were 336.

IRELAND.

The death rate represented by deaths from puerperal septic diseases in Ireland during the year 1905 was 2·21 per 1000 births registered; during 1906 it was 2·26; and during the year 1907 the rate was 1·60 per 1000 births registered. In 1884 the deaths from puerperal fever and phlegmasia dolens represented a rate of 2·57 per 1000 of all births registered in that year.

(B) *Operative Midwifery.*

During the last quarter of a century the employment of antisepsis and asepsis and the experience derived from abdominal surgery, due so largely to gynæcologists, have exercised a marked influence upon operative midwifery. *This is well seen in our present knowledge of the patho*logy and treatment of extra-uterine pregnancy, in the revival of symphysiotomy and its more recent modification must care for the child. Now, in reference to the latter he must concern himself, not only with those factors that promote and favour antenatal life, but he must also have a thorough acquaintance with the means for preserving the life and promoting the growth and welfare of the newborn infant. The ideal we must all aim at in our practice, as I pointed out at the beginning of this address, is not alone the absence of *mortality*—that is, a living mother and a living child—but, at the same time, the avoidance of *morbidity*—that is, a healthy mother and a healthy child. If this ideal-it to be realised it is absolutely essential—above and beyond the expert aid and advice afforded by the skilled obstetrician—that there should be spread more and more among the people the knowledge of motherhood. We must train the children in the public schools as to what is essential for the proper understanding of life, so that they may realise how often Browning's line is true:—

---

[6] Geschichte [illegible] Wiener und [illegible] Hofrat [illegible] 909

> "Ignorance is not innocence but sin."[14]

Those who are brought face to face with the clamant public health problems of our great cities—and in the boroughs and urban districts of England and Wales there were 77 per cent. of the aggregate population in 1901 as compared with 50 per cent. in 1851—must feel that if we are to succeed in making a healthy nation, if we are to get rid of that physical degeneration which is so prevalent, and if we are to regain our ability and our energy—qualities which are so essential for any country in the present fierce struggle for existence, and so much of which has been lost through crime, ignorance, and apathy—we must cease to neglect the mothers of our people. No method will ever give us physical betterment which does not exercise a beneficial effect upon that sex which is the most dominant element in the development of the race. The more in every respect we elevate motherhood, the more we dignify home and the more we raise our race.

Now, in order to spread the knowledge of what is really essential for good motherhood among the poor—especially of our crowded cities—we must insist that at the public schools the laws of health and hygiene are taught, and in connexion with these schools the establishment in Ireland recently of the Girls' Guild of Good Health (which is in affiliation with the Women's National Health Association of Ireland) is a distinct step in advance. The girls banded together in these guilds pledge themselves to be as healthy as possible in body and mind. We must also try to reach a class hitherto totally neglected—the poor expectant mothers—and to guide them in reference to such questions as food, occupation, housing, and temperance—factors so important not alone to themselves but to their unborn children, for it is well known that four-fifths of the value of an infant's start in life and its chance of living depend upon the proper nutrition of its mother during her pregnancy. Truer words were never uttered by any statesman than those spoken by the President of the Local Government Board when, in a discussion in reference to the administration of his department in the House of Commons on June 17th of this year, he said: "It was the business of every employer of labour, of every husband and wife, and of every department and authority concerned in the future of the race, to see that the prenatal conditions of the child were vastly improved."

In his interesting address last week at Leeds on Child Mortality in Relation to the Health of the State, Dr. George Newman, Chief Medical Officer of the Board of Education in England, said that future measures of preventive medicine must start from the child and must deal with the home. Now, while both these means are admirable, unless the antenatal conditions are improved, even these efforts, good as they are, will, in many cases, come too late.

Such aid, in addition to useful hints on various points, might in some cases take the form of good nourishment, especially during the latter half of gestation, outfits ("maternity bags"), &c., for those who do not enter lying-in hospitals. In some places this help can be, and indeed is, afforded through voluntary philanthropic agencies, such as guilds of lady visitors, mothers' welcomes, babies' clubs, Samaritan funds, and maternity nurses; but looking at the way France, with her low birth-rate (and we must not forget that in England and Wales only two children are now born against the three of 30 years ago), has been compelled to face the problem, it is a question whether optional powers (as in Mr. Robert Harcourt's Necessitous Mothers' Assistance Bill, introduced this session) should not be given to local authorities to levy a special rate for this purpose.

I have shown that in modern times properly conducted maternities have banished that great scourge formerly styled puerperal fever, and it is to the credit and glory of obstetric medicine that it was Pierre Budin, professor of midwifery in the University of Paris and director of the Clinique Tarnier, who in 1892 started a similar revolution in the interest of the new-born child by establishing the first fully developed "Consultation for Nurslings," or School for Mothers. At a great congress of artisans in Paris in 1892 Budin said: "Your country has need of all her children, and humanity demands that we should spare no effort on their behalf." Shall we not repeat these words in every part of our Empire? Here in Belfast we are making a beginning, for in connexion with the infant mortality committee of the Belfast branch of the Women's National Health Association of Ireland, that splendid organisation established by Her Excellency the Countess of Aberdeen, whose magnificent work on behalf of public health in Ireland is known all the world over, there has been started a series of schools for mothers called "babies' clubs." They now number four, situated in different parts of the city, and they are the first of the kind in Ireland, and are doing an immense amount of educative work in spreading the light in regard to good motherhood and in solving the infantile mortality problem. These admirable organisations are in close touch with the Belfast Maternity, the two children's hospitals, the dispensary midwives, the St. Vincent de Paul Society, the Nurses of Charity, and numerous other philanthropic societies of our city. They are managed by a small band of most devoted ladies whose great aim is to afford practical help to poor, necessitous, and inexperienced women, and to bring before them the knowledge necessary for good motherhood. They show them how properly and hygienically to bathe, clothe, and dress babies, and how to laundry their garments. They encourage in every possible way the mothers to nurse their children, but in case of insufficiency or of total failure in this respect they supply them with milk which comes from a dairy where, by the tuberculin test, cows suffering from tuberculosis are excluded, where modern clean Danish methods are used with rapid cooling of the milk, which is placed in sealed bottles. This milk, following the method of the famous Copenhagen Milk-supply Company, is neither pasteurised nor sterilised, and by an arrangement with the proprietor of the dairy it is sent direct to the homes of the women whose children, in the opinion of the lady doctors who attend the clubs, really require it; but this milk is given only on condition that the infants are brought every week to the clubs so that it may be judged how they are progressing. These babies' clubs are thus doing a threefold duty: (1) they are educating the mothers; (2) they are supplying, when needed, a pure milk; and (3) they are affording an object lesson, even before the passing of Mr. Burns's Milk and Dairies Bill, as to the production of a natural, clean, non-tuberculous milk. Since the opening of the first club in February, 1908, up to July 1st, 1909, 889 children have passed through these institutions, and 5640 quarts of pure milk have been distributed. In the summer of last year—July, August, and September—I am informed, not a child receiving this milk died. To the young expectant mothers hints are given as to the care of themselves, and they are advised as to making provision for their confinement.

Further, from a public health point of view, the Midwives Act of 1902 should be made to apply to the whole of the United Kingdom, and not, as at present, to England alone. Ophthalmia neonatorum, a preventable malady, which is the cause of at least one-third of the cases of permanent and hopeless loss of vision in our blind institutions, should be constituted a notifiable disease; and provision should be made for the early removal of cases of puerperal infection among the poor to hospitals or institutions where the results of the latest scientific research can be made available, and effective treatment can be employed.

(3) *Problems still Unsettled, requiring for their Solution the Combined Efforts of the Obstetrician, the Biochemist, and the Clinical Pathologist.*

We have accomplished much in the last quarter of a century, but there are still many questions in obstetrics that await solution. How little we yet know as to the real nature of menstruation! Is dysmenorrhœa a disease, or is it a symptom of many underlying conditions? What is its relation to sterility? What a field the diseases of pregnancy afford to the careful scientific investigator! We speak of the toxæmias of pregnancy, but what are these toxins and how and where are they elaborated? What are the factors in *the production of herpes* (*hydroa*) *gestationis*? What really is eclampsia? How does tubal pregnancy occur? What is the cause of chorion-epithelioma? How do diseases of the placenta arise? Why are women at childbirth so susceptible to bacterial infection? Why do the bacteria travel at one time along lymphatics, at another in the course of blood-vessels? We know that puerperal infection is caused by micro-organisms, but how do these microbes become virulent and in what way do they lose their malignant influence? Has season, race, or the predisposition (lowered resistance to infection) of the individual attacked anything to do with their power? In other words, while we know a great deal about the seed we are still largely in the dark as to the soil. No doubt operative interference has accomplished much in puerperal infection, especially in cases of localised abscess, pus tubes, and intense peritonitis limited to the pelvic organs, and occasionally in ligation or excision of thrombosed veins in puerperal pyæmia (as has been done in infected thrombi in mastoid disease);[15] still, when severe puerperal infection is present, can we yet boast of having advanced much beyond the view of William Hunter, who said, "Treat these in what manner you will, at least three out of every four will die." Have our surgical measures accomplished much in the very severe types of puerperal infection? Speaking for myself, in the most fatal and formidable form of puerperal infection—that due to the streptococcus pyogenes—I have seen little advantage so far from surgical interference. The serum treatment of puerperal infection has also been disappointing clinically; and, indeed, with the exception of the antidiphtheritic and the antitetanic serums, is the preparation of the various antibacterial serums based on exact scientific principles? Certainly no one should use an antibacterial serum "except where, as in the case of an antidiphtheritic serum, the pathologist is prepared to give him definite information with respect to the amount of protective substances in the serum."[16] Is the future of these severe puerperal infection cases, so far as treatment is concerned, not with that school established by one who received his early *education in Belfast, Sir Almroth Wright*, and his pupils, whose work is revolutionising every branch of medicine, and who from each case of puerperal infection may elaborate the proper vaccine-therapy?

---

[14] The Town Album.

CONCLUSION.

We must invoke in the future, more and more, the help of the physiological chemist and of the clinical pathologist in the clearing up of the many unsolved problems of obstetric medicine, and they must work hand-in-hand with the practical obstetrician. It is in the laboratory situated in the maternity hospital that investigators, I am convinced, will help the practical obstetrician to unravel in the years to come many of these mysteries that still confront us, but they must look at these problems both from the clinical as well as from the biochemical and from the pathological side, and, as a result of the combined efforts of all these workers, may we soon be able to say—

"There's a fount about to stream,
[illegible]
Men of thought, and men of action,
Clear the way!

Once the welcome light has broken,
Who shall say
What the unimagined glories
Of the day—
What the evil that shall perish
In its ray?
. . . . . .
. . . . . .
And our earnest must not slacken
Into play.
Men of thought, and men of action,
Clear the way!

Lo! a cloud's about to vanish
From the day,
And a brazen wrong to crumble
Into clay.
Lo! the right 's about to conquer;
. . . . . .
. . . . . .
Men of thought, and men of action,
Clear the way!" —*Charles Mackay.*

The Hunterian Lectures

ON

MALFORMATIONS OF THE HEART.

Delivered before the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1909,

By ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng.,

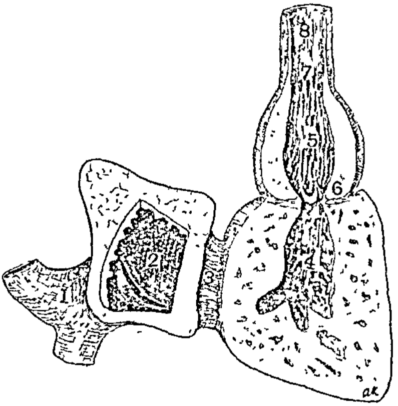
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND CONSERVATOR OF THE MUSEUM.

LECTURE I.

Delivered on March 8th.

Mr. President and Gentlemen,—Although it is 43 years since the last edition appeared, Peacock's treatise on "Malformations of the Human Heart" still remains the standard English work on this subject. It is as fresh as the day on which it was written, for it is founded on accurate personal observation by the bedside and in the post-mortem room. After his death in 1882, the collection of malformed hearts which he had treasured and studied was presented to this Museum and forms a very important part of the series of specimens which I now bring before you as the subject matter of these three lectures.

Fig. 1.



The four primary chambers of the heart, from a specimen (heart of Xiphias gladius) in the Museum of the Royal College of Surgeons of England. 1, Sinus venosus; 2, auricle laid open showing the venous valves guarding orifice of sinus; 3, auricular canal; 4, ventricle; 5, bulbus cordis; 6, ventricular orifice of bulbus; 7, aortic orifice of bulbus; 8, common ventral aorta leading to gills.

Our knowledge of the heart has advanced since Peacock's time. One of the greatest discoveries of that period is now only dawning, but every year increases our assurances of its truth—viz., that there is a fourth part or chamber in the mammalian heart which hitherto we have taken no cognisance of. The three parts of the mammalian heart at present recognised are (1) the sinus venosus, (2) the auricles, and (3) the ventricles. The fourth part is the bulbus cordis, which is so well seen in the shark's heart. (Fig. 1.) It is usually supposed that the bulbus cordis has completely disappeared from the mammalian heart, but now we have good reason for believing that, in the same manner as the sinus venosus has become incorporated in the right auricle, the bulbus has become included in the right ventricle, forming that part loosely termed its infundibulum.[1] The credit of this discovery belongs to Alfred Greil,[2] prosector in the University of Innsbruck. He traced the fate of the bulbus by a prolonged study of the hearts of developing vertebrates. Independently of him I had reached the same conclusion from an investigation of malformed human hearts and of the hearts of vertebrate animals. Professor Peter Thompson[3] has recently identified and described the development of the bulbus in an early human embryo. A large number of the very commonest malformations of the human heart are due to an arrest of the process which ends in the incorporation of the bulbus cordis in the right ventricle. The great majority of cases of congenital stenosis of the pulmonary artery are of this nature.

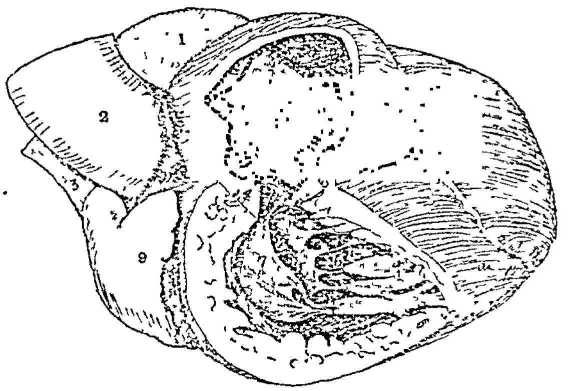
[16] A Criticism of the Foundations of Serum-Therapy, by Sir A. E. Wright, in Studies on Immunisation, 1909

The 55 malformed hearts in the College Museum form the subject matter of my discourse, but my inferences are founded on a wider basis. Thanks to the liberality and courtesy of those who are responsible for the management of the museums of the metropolitan medical schools, I have had an opportunity of examining the specimens in their collections. Through Professor T. Wardrop Griffith—a leading authority on malformations of the heart—I have been able to examine the splendid collection in the museum of the University of Leeds. From these various sources and from my own dissections a series of over 270 specimens is included in the material with which I now deal.

1. SUB-DIVISION OF THE RIGHT VENTRICLE.

The first malformation I propose to consider is the comparatively rare one usually described as sub-division of the right ventricle. There are three specimens in the museum, and Dr. John Hay has recently presented a fourth. The heart, however, which I propose to describe as the type is one which Dr. Percy Kidd gave me the opportunity of examining. It is shown in Fig. 2. The body of the right ventricle is separated from its infundibulum by a muscular partition, the centre of which is perforated by a foramen large enough to take the little finger. The margin of the foramen is composed of fibrous tissue. The infundibulum is dilated and larger than in the normal heart. The semilunar pulmonary valves are normal. On the septal wall of the infundibulum is seen an important fibrous raphe extending from the semilunar valves above to the constriction or ostium infundibuli below. Below the ostium, in the position of the pars membranacea septi, there is a small foramen—the interventricular—by which blood in the body of the right ventricle could have passed into the left ventricle, or *vice versâ*, during life. There are 19 hearts with malformations of this nature in the series which I have examined. Two of these in the College collection are peculiar; the muscular partition between the two parts of the right ventricle is wholly muscular, and in one the infundibular chamber has reached the apex of the heart. The normal heart shows a muscular constriction at the junction of body and infundibulum of the right ventricle, a fact to which Peacock had drawn attention. The moderator band, which we now know to be a muscular bridge for the conduction and protection of the right septal division of the auriculo-ventricular bundle, forms part of the musculature of the constriction.

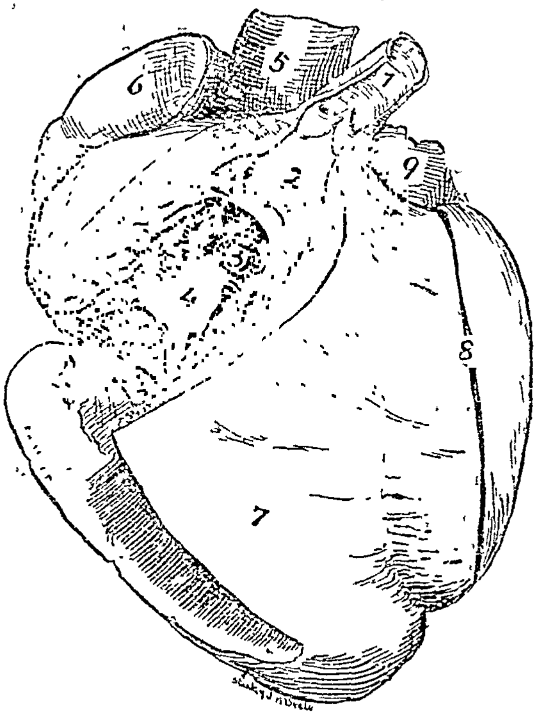
FIG. 2.



Heart of a man, aged 20 years, who died after two months' illness from acute infective endocarditis, showing subdivision of the right ventricle. 1, pulmonary artery; 2, aorta; 3, superior vena cava; 4, 5, on margins of lower ostium infundibuli—the interventricular orifice is seen between 4 and 5; 6, body of right ventricle; 7, tricuspid valve; 8, left ventricle; 9, right auricle, A, right infundibular band; B, left infundibular band.

The majority of patients with this malformation of the heart live to adult age; indeed, in some the condition is only discovered after death. The symptoms depend on the size of the ostium infundibuli. In some it measured only from 2 to 4 millimetres in diameter, leading to early death, but in the greater number the orifice measured from 6 to 15 millimetres in diameter. The maximum intensity of the systolic bruit heard in such cases lies to the right of the sternum below the insertion of the fourth costal cartilage. In nine cases there was an interventricular foramen present (see Fig. 2), so that the blood in the body of the right ventricle, obstructed by the narrow ostium infundibuli, might also escape into the left ventricle. In four cases there was also a union or stenosis of the pulmonary semilunar valves; in three the ductus arteriosus was patent and in two the foramen ovale. In quite a large number the fibrous margin of the ostium infundibuli was covered by vegetations—a fact which led to the inference that the fibro-muscular partition between the infundibulum and body of the right ventricle is not a malformation but a cicatricial constriction. It is well known that the right side of the heart becomes more liable to endocarditis than the left if there are obstruction and hypertrophy on that side. The endocarditis is a result, not a cause, of the ostium infundibuli.

FIG. 3.



Heart of a girl, aged seven years, showing arrest in the expansion of the infundibulum (drawn by Mr. Stanley J. A. Beale). 1, Pulmonary artery [illegible] separated from body of right [illegible] partition which is perforated [illegible] 3, interventricular orifice; 4, [illegible] auricle; 7, right ventricle; 8, left ventricle; and 9, left auricle.

---

[3] Journal of Anatomy and Physiology, 1907, vol. xli., p. 159.

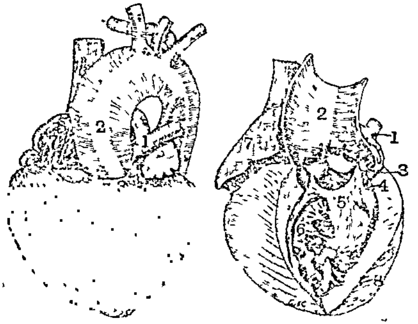
2. CASES IN WHICH THE DEVELOPMENTAL EXPANSION OF THE INFUNDIBULUM IS ARRESTED.

We now pass on to a group of cases which occur much more frequently than those just considered and are usually classified under the term "congenital pulmonary stenosis" In reality they represent a condition in which the arrest in the development of the infundibulum is much more complete than in the last series. The heart shown in Fig. 3 may be taken as representative of this group—hearts in which there has been an arrest in the developmental expansion of the infundibular cavity. In the type specimen (Fig. 3) the infundibular cavity is fusiform in shape, measuring 12 millimetres from the orifice by which it communicates with the body of the right ventricle (the ostium infundibuli) to the pulmonary valves above. The lining of the infundibular cavity has the appearance of ground glass because the subendocardial tissue is fibro cellular in texture, and embryonic rather than inflammatory in its microscopic structure. The ostium infundibuli may be as well marked as in the type specimen (Fig 3), or it may be indicated merely by a circular thickening of the endocardium, or even that indication may be absent. The pulmonary valves in less than half of the hearts of this nature which I have examined—44 in number, of which 16 are in the College collection—were *fused to a greater or less degree, the condition of arrest of* the infundibulum being thus accompanied by a true pulmonary stenosis. In more than half of these cases—I do not give the exact numbers because in some of the specimens examined the heart was insufficiently opened—an interventricular foramen was present; the size of that foramen was variable. In only a small percentage was there an open condition of the foramen ovale or ductus arteriosus.

3. HEARTS IN WHICH THERE IS ALMOST COMPLETE ARREST IN THE DEVELOPMENTAL EXPANSION OF THE INFUNDIBULUM.

A third group of cases represents an almost complete developmental arrest of the infundibulum. The typical condition is shown in Figs. 4A and 4B, drawn from a specimen presented to me by Dr. J. A. Milne. The infundibulum is represented by a mere slit or irregular chink situated at the orifice of the pulmonary artery and lined by thickened endocardium. The orifice of the pulmonary artery may be represented by merely a small cicatricial mass or a very small lumen may be present in which the fused semilunar valves can be distinguished. The pulmonary artery, perhaps represented by a fibrous thread at its origin, rapidly increases in calibre as it passes into its point of division into right and left branches An intraventricular foramen is always present, but only in about 30 per cent. of the cases—which numbered 37 in all—was there a patency of the ductus arteriosus.

FIG. 4.



Heart of a girl, aged two years, showing complete arrest of

In such cases the branches of the pulmonary artery are very thin-walled and often greatly dilated. How are they filled with blood in such cases? The orifice of the pulmonary artery is closed or almost closed Dr. Bertrand E. Dawson gave me the opportunity of injecting the arteries in a case where there was marked congenital pulmonary stenosis. The bronchial arteries and other accessory branches derived from the intercostals were so enlarged that some of them were equal in size to the radial arteries, but one was especially struck by the number rather than by the size of the accessory arterial communications; they formed a leash like plexus. The arteries accompanying the phrenic nerves were greatly enlarged and sent branches to the lungs. In those cases where there is complete arrest of the infundibulum, the arterial system of the lungs is filled from the systemic circulation To merely live—and that is the condition of patients with such hearts—a wonderfully small supply of oxygenated blood is apparently sufficient.

4. CASES IN WHICH THE STENOSIS IS MERELY DUE TO FUSION OF THE SEMILUNAR VALVES.

In my list of specimens I have noted 23 in which there was apparently no developmental arrest of the infundibulum yet the pulmonary semilunar valves were united, giving rise to a true condition of pulmonary stenosis Five of the specimens on my list are in the College collection, but when they were taken out of their jars and examined it was seen that in four of them there was an arrested condition of the infundibulum. It is very probable that if all specimens of this nature were so displayed as to show the infundibular part of the right ventricle there would remain only a few in which pulmonary stenosis is present by itself. Still, the condition does occur and is the only form which one could conceive to be the result of a fœtal endocarditis In Figs. 5 and 6 is shown the usual condition of the valves. They are fused so as to form a bell-shaped perforated diaphragm. In most cases traces of only two valves can be made out, but occasionally a third can be distinguished.

FIGS. 5 AND 6.

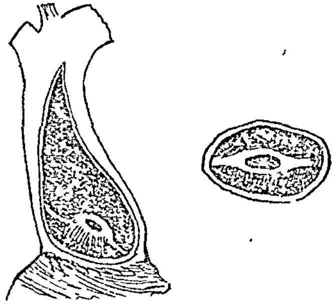


FIG. 6 —Pulmonary valves exposed by opening the pulmonary artery in a case of arrested development of the in- … of stenosis

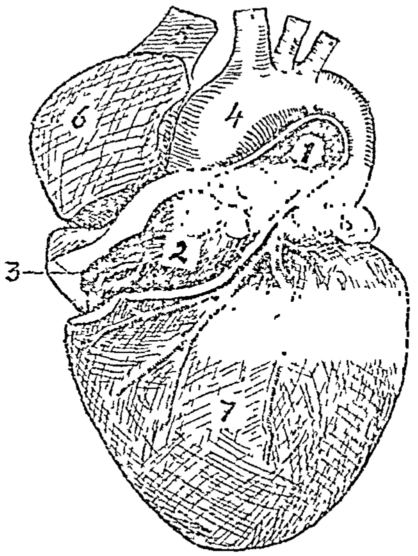
of stenosis exposed
ery just above the

Many patients who suffer from pulmonary stenosis die from broncho-pneumonia or other forms of infection; in such cases it is usual to find the margin of the pulmonary orifice carpeted with vegetations. It is difficult, however, to conceive that the peculiar form of the pulmonary valves in these cases could result from an inflammatory condition in the fœtus The condition is totally unlike the stenosis which occurs after birth. Under the microscope the valves, in cases of congenital pulmonary stenosis, are seen to be composed of dense laminated fibrous tissue at their margins, but the body of the valves shows a reticulated tissue distinctly embryonic in character.

5 CASES IN WHICH THE INFUNDIBULUM IS PRESENT AND THE BODY OF THE RIGHT VENTRICLE IS SMALL OR ABSENT.

The group of cases I am now going to describe illustrates further the dual constitution of the right ventricle. The type specimen of this group is shown in Fig. 7, drawn from a heart sent to me by Dr. F. S. Mackenzie. Here, while the infundibulum of the right ventricle is well developed the body of that chamber is atrophied or obliterated. The condition is usually accompanied by a congenital stenosis or complete obliteration of the right auriculo-ventricular orifice. In such cases the foramen ovale is patent, so that the venous blood can pass from the right to the left auricle and ventricle. From the left ventricle part of the blood passes into the infundibulum by a patent interventricular foramen. There is also another form in which the infundibular cavity is present and the body of the right ventricle is apparently absent—namely, those cases where the right and left ventricles are unseparated by an interventricular septum. Of the seven specimens belonging to this group five are cases in which the right ventricle is obliterated, two in which the two ventricles form a common chamber.

FIG. 7.



Heart showing infundibulum developed but the body of the right ventricle atrophied. 1, Pulmonary artery opened; 2, infundibulum opened; 3, ostium infundibuli, leading by an interventricular foramen into left ventricle, 4, aorta; 5, superior vena cava; 6, right auricle; 7, left ventricle; and 8, left auricle.

6. CASES OF SUBAORTIC STENOSIS.

Turning now to the left side of the heart, a condition—very rare, it is true—is found similar in nature to the malformations just described on the right side with this difference. The part of the fœtal heart from which the infundibulum is derived—the bulbus cordis—normally disappears completely from the left side of the heart, but a trace of it may persist giving rise to the condition known as subaortic stenosis—a condition which has hitherto not received a satisfactory explanation. Thus, while the abnormality on the right side of the heart depends on an arrest of growth, that on the left side depends on an arrest of atrophy. The type specimen, which belonged to the museum of the London Hospital, and was lost in the disastrous fire at Toronto University, is shown in Fig. 8. Just below the orifice of the aorta a fibrous collar is seen to surround the infundibulum of the left ventricle. It is formed by an irregular thickening of the endocardium. The ostium infundibuli is in every way homologous to the corresponding abnormal constriction which occurs in the right ventricle. I have seen only four hearts showing subaortic stenosis—one in the museum of St. George's Hospital, one in St. Bartholomew's, one in Guy's, and the one figured here. We have, unfortunately, no specimen in the College collection.

7. CASES OF CONGENITAL AORTIC STENOSIS.

The condition of congenital aortic stenosis is rare in England. Altogether I noted only four cases in the museums of the metropolitan medical schools. The malformation is apparently much more frequently seen in St. Petersburg, for in 106 malformed hearts Therémin found this abnormality 17 times. Among 14 stillborn children—all of them showing marked deformity of the body with malformation of the heart—I observed aortic stenosis in only three of them, two of these being in children of Polish Jews.

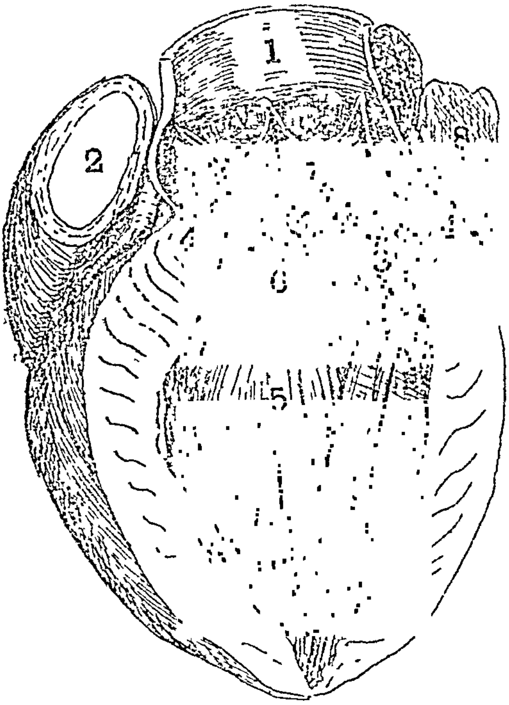
SUMMARY OF CASES OF MALFORMATION OF THE BULBUS CORDIS.

So far I have dealt with malformation of the heart in the vicinity of the origins of the pulmonary artery and aorta—the part into which the bulbus cordis is incorporated. The cases fall into seven groups:—

1. Incomplete fusion of the infundibulum with the body of the right ventricle	19 cases.
2 Partial arrest in the development of the infundibulum	44 ,,
3. Complete arrest of the infundibulum	37 ,,
4. Fusion of pulmonary semilunar valves	23 ,,
5. Partial or complete absence of the body of the right ventricle with development of the infundibulum ...	7 ,,
6. Subaortic stenosis	4 ,,
7. Aortic stenosis	7 ,,

Altogether 141 cases out of a total of 272 malformed hearts are imperfect because of a lesion connected with the transformation of the bulbus cordis during the development of the embryo.

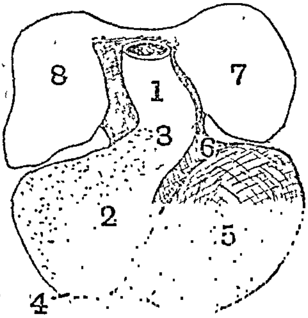
FIG. 8.



Heart showing subaortic stenosis (heart of man, aged 20 years) 1, Aort[illegible] 3, mitral valve; 4, 4, fibrous [illegible] ortic vestibule; 5, interventrici[illegible] of septum below ring; and 7, non-coronary cusp of aortic orifice, site of endocarditis

Applying now our present knowledge of the development and comparative anatomy of the heart to the explanation of these abnormalities, we find ourselves hampered at the very outset by a complete ignorance of the functional nature of the bulbus cordis. It is especially large in the shark tribe and is often lined with valves and thickened endocardium throughout (Fig. 1). Its musculature is striated but the fibres are more fusiform and less branched than in the other chambers. The nerve-supply is abundant. Systole occurs in it subsequent to contraction in the ventricles. Somehow its function is connected with the gill or respiratory system; it is with the respiratory system that it is correlated. When the gills become replaced with lungs and the aortic stem divided into systemic and pulmonary trunks as in the amphibia, the part of the bulbus at the origin of the aorta atrophies more than the part connected with the pulmonary artery. In reptiles a part of the bulbus musculature persists and can be distinguished from the proper ventricular muscle; I have also seen it well marked in an abnormal human heart. In the hearts of birds and mammals the bulbus musculature completely disappears, but its cavity persists, undergoes a great expansion, and forms the infundibulum of the right ventricle. How far the infundibulum is formed by a downward expansion of the bulbus cavity into the right ventricle and how far it is formed by an upgrowth over it of the ventricular muscle is difficult at present to decide, but the evidence of malformed hearts points to the former process being the true one. What the exact function of the infundibulum of the mammalian right ventricle may be is difficult at present to say, but its origin, its comparative anatomy, and the arrangement of its musculature make *it certain that it has something to do with the* [illegible] There are many [illegible] of the heart [illegible]

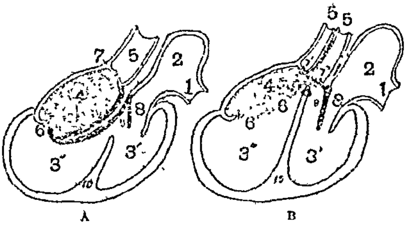
FIG. 9 A.



[illegible] right auricle.

The embryological transformation which occurs at the aortic end of the cardiac tube during the latter part of the first, and earlier part of the second, month of development is very remarkable. In Fig. 9, A and B, are shown side by side the heart of a human embryo, probably about 21 days old, reconstructed and described by the late Professor His, and that of a shark. The bulbus cordis, from which the primitive aorta springs, is still well demarcated from the ventricular part of the tube—just as in the shark's heart. The ventricle at this time has, like the stomach, a greater and lesser curvature. As development proceeds a rapid atrophy of the lesser curvature sets in, so that the bulbus comes in contact with the auricular canal, just as an atrophy of the lesser curvature of the stomach would bring the pylorus against the œsophagus. The atrophy also involves the corresponding or lesser curvature of the bulbus. When the primitive aorta becomes divided into aorta and pulmonary artery, the aorta is found to be connected with the lesser curvature of the bulbus and ventricle—where the bulbus atrophies, while the pulmonary artery, being situated towards the greater curvature, is connected with the par which persists.

FIG. 10.



To show the manner in which the bulbus cordis becomes incorporated in the mammalian heart and forms the infundibulum of the right ventricle. A. The bulbus as a separate chamber. B. The bulbus as incorporated in the right ventricle. 1, orifice of sinus venosus; 2, auricles; 3, 3', left and right ventricles; 4, bulbus cordis; 5, common [illegible] s (in B it becomes [illegible] lesser curvature, [illegible], aortic orifice of [illegible] anterior cusp of mitral; 10, interventricular septum.

The diagram given in Fig. 10 will help to make this transformation better understood. In the shark's heart one recognises the *constriction or orifice between it and the common* ventricle—the ostium bulbi. The ostium bulbi is usually provided with valves; the pulmonary and aortic semilunar valves represent those at the aortic orifice of the shark's bulbus. In the process of development, as Fig. 10 shows, the ostium bulbi becomes stret[illegible] the interventricular septum; t[illegible] side of the septum forms the c[illegible] to the left may persist and form the subaortic constriction. The embryological and comparative evidence make it certain that the bulbus is incorporated in the ventricle of the heart; the ostium infundibuli in the right ventricle of abnormal hearts and the subaortic constriction on the left occupy the position at which the ostium bulbi should occur. In brief, the theory of the bulbus cordis explains a great number of abnormal conditions hitherto inexplicable.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Joseph Chapman of Grimsby the Brompton Hospital for Diseases of the Chest, the London Hospital, the Middlesex Hospital, the St. Mark's Hospital for Fistula, and the Grimsby District Hospital will each receive a net sum of about £25,000.—The late Mr. Arthur Campbell of Edinburgh bequeathed £[illegible] to the Hospit[illegible] the Royal V[illegible] and £500 to t[illegible]

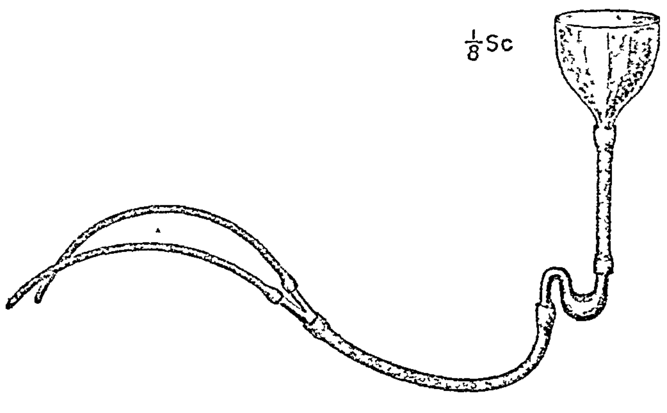
THE MEDICO-LEGAL SOCIETY.—The eighth annual general meeting of this society was held at 22, Albemarle-street, W., on July 27th, Dr. W. Wynn Westcott (vice-president) being in the chair. The annual statement of accounts was presented by Mr. Schröder (honorary treasurer) and approved. Mr. Digby Cotes-Preedy read the honorary secretaries' report, which showed that the membership of the society now numbered 238, 67 new members having been elected during the year. Votes of thanks were passed to Sir Joseph Walton, the retiring President, and officers. Sir John Tweedy was elected President for the coming year, Mr. Walter Schröder was re-elected honorary treasurer, and Mr. Cotes-Preedy and Mr. William A. Brend were re-elected honorary secretaries. The meeting discussed and amended certain rules of the society.

A METHOD OF GIVING ETHER BY MEANS OF NASAL TUBES.

By H. M. PAGE, F.R.C.S. Eng.,
ANÆSTHETIST TO GUY'S HOSPITAL, ETC.

Dr. George Crile of Cleveland, Ohio, devised this method for administration of ether in cases of removal of the tongue and of operations for malignant disease of the mouth, and in extensive dissections for secondary disease in the neck. The advantages claimed by Dr. Crile after a large experience are that a laryngotomy is avoided; that no blood or septic material is inhaled, and therefore the risk of bronchitis and pneumonia is eliminated; that the anæsthetist is altogether out of the way of the operator; and that in the neck cases asepsis can be more certainly attained than by the other methods in use for anæsthetising these cases. Though the number of cases in which I have used this method has been small I venture to publish an account of them, as I do not find the method described in the English text-books on anæsthetics, and I think it deserves further trial and to be better known over here. I have also for the same reasons fully described the technique of the method.

The apparatus necessary is very simple and has been most satisfactorily made for me by Messrs. Down Bros. from a photograph which Dr. Crile was kind enough to send me. It is shown in the accompanying illustration. It consists of two indiarubber tubes sufficiently large to closely fit the nares; these nasal tubes are coupled to a much larger indiarubber tube by means of a Y-shaped piece of glass-tubing; this larger indiarubber tube is connected with a large glass funnel which is covered with a single layer of thin flannel, and it is interrupted in its course by a glass trap to prevent any excess of ether running down the nasal tubes.



An injection of morphine and atropine is given an hour before the operation. I have used $\frac{1}{4}$ gr. and $\frac{1}{75}$ gr. respectively. Ether anæsthesia is induced by the open drop method, the mouth is then opened, and the pharynx and pharyngeal aspect of the epiglottis and larynx are brushed over with a 2 per cent. solution of cocaine, and the closely fitting indiarubber tubes are pushed down the nares till the lower ends are opposite the epiglottis. The pharynx is then packed with a roll of sterilised gauze whilst the tongue is being pulled forward. In packing, care must be taken not to compress the tubes, though it must be done thoroughly, and the lateral parts of the pharynx to the outer sides of the tubes must not be neglected. Ether anæsthesia is now maintained by the drop method on the flannel covering the glass funnel. It is a help to get some one to begin dropping ether on the flannel as soon as the nasal tubes are passed and so prevent to some extent the lessening of anæsthesia which must occur whilst the packing, &c., of the throat is being done. A sterilised towel is thrown over the head of the patient, completely covering it. The anæsthetist stands about two feet behind the patient. The breathing and the colour of the blood at the site of the operation are watched and an occasional look at the patient can be taken by raising the towel without interfering with the operator. It would be quite easy to give a little oxygen by passing a tube through the flannel, but this has not been called for in the cases I have anæsthetised. As to the rate of dropping the ether, less ether was required than in the ordinary way of using the open drop method.

The first case was one of extensive dissection of the neck for malignant disease secondary to that of the tongue. The second case was one of removal of half of the tongue subsequent to the above operation. On this second occasion the patient was anæsthetised by Mr. George Rowell. I was present only at the beginning of the operation, but Mr. Rowell writes as follows: "The method answered well. The patient kept a good colour, while his breathing remained free and was unaffected by inconvenient reflex action during all the time that the tubes were in position. Very little ether was needed to maintain this degree of narcosis, and at the end of the administration recovery was rapid."

In the third case an extensive operation for clearing the neck for secondary disease was first done, and then half of the tongue was removed at one sitting. Shortly after beginning the dissection of the neck it was noticed that the blood was rather dark at the site of operation, and on raising the towel some cyanosis of the face was found, so the mouth was opened, the gauze packing removed, and the pharynx repacked, after which the colour kept quite good for the rest of the operation. One of the tubes may have been somewhat compressed. The operation was not delayed for more than two minutes.

As far as the anæsthetist was concerned the cases of removal of the tongue presented no difficulty and caused less anxiety than when the tongue is removed under other methods of anæsthesia, especially when a preliminary laryngotomy is not done. The patient in each case had recovered all the reflexes and spontaneous movement and was almost conscious when removed from the operating table and could be sat up in bed immediately. I should say that this condition of the patient is easier to ensure after a long operation by this method than when chloroform has been given. The third case, in which the whole operation was done at one sitting, was naturally a long one and liable to be followed by a good deal of shock, but there was practically no shock at all. I do not think the method could be used when the whole of the tongue down to the epiglottis is to be removed as there would not be enough hold left for the packing. Mr. W. Arbuthnot Lane and Mr. C. H. Fagge, who operated on these cases, have authorised me to say that the method gave a very free access to the site of operation owing to the anæsthetist being altogether out of the way, that antiseptic precautions were facilitated, that hæmorrhage was not troublesome, and that each patient made an uneventful recovery.

I have used Crile's nasal tubes on two other occasions with chloroform instead of ether. Chloroform had to be employed as fulguration was to be done after the removal of the malignant disease from the neck. Morphia and atropine were injected, anæsthesia was induced with chloroform, the pharynx was cocainised, and the nasal tubes were passed and the pharynx packed as before. The nasal tubes were then coupled up with a Vernon Harcourt inhaler and chloroform administered with a small quantity of oxygen. The anæsthesia gave no trouble whatever on either occasion, the air-way and the working of the valves being more satisfactory than in some cases in which the Vernon Harcourt inhaler is used with the face-piece. The patient on each occasion kept a perfect colour, and though each administration, owing to the fulguration, lasted nearly two hours, movement and phonation had returned before the patient left the table. A faint corneal reflex was allowed to persist the whole time, but the patient was absolutely still and there were no reflex effects on respiration or circulation. The strength of chloroform vapour used was in the first operation from my notes: "Most of the time $\frac{1}{2}$ per cent., part of the time $\frac{1}{4}$ per cent., never more than 1 per cent." In the second administration: "2 per cent. was used at first for a short time, after which the indicator varied between $\frac{1}{4}$ per cent. and 1 per cent., being most of the time at $\frac{1}{2}$ per cent." The two operations were on the same patient and there was a good deal of after-vomiting for 12 hours on each occasion. This did not occur in the before-mentioned cases in which ether was used.

Grenville-place, S.W.

(I.) PRESSOR BASES IN NORMAL URINE AND THEIR DIMINISHED EXCRETION IN GOUTY URINE; (II.) THE EXCRETION OF CHLORIDES IN GOUT.

BY WILLIAM BAIN, M.D. DURH., M.R.C.P. LOND.
(From the Physiological Laboratory, King's College, London.)

I.

IN 1906 Abelous and his colleagues[1] obtained from putrid horse-flesh a base which produced a rise of arterial blood pressure when injected intravenously. Abelous also obtained a base with similar properties from normal urine which he named "urohypertensine," and he suggested that it was the same substance as that obtained from putrid meat. In March of this year Rosenheim,[2] who worked with putrefying placenta, and Barger and Walpole,[3] who, like Abelous, worked with putrid flesh, were able to isolate the pressor material and show that it consists of several bases, two of which were identified with certainty. One of these, iso-amylamine, is formed from leucine, and the other, *p*-hydroxyphenylethylamine, is derived from tyrosine. The second is the more powerful agent and is related chemically to adrenaline. If pressor bases originate by putrefaction outside the body it is probable that similar substances are produced by putrefaction within the intestinal canal. In fact, Abelous and Bardier[4] have more recently found their "urohypertensine" in the fæces. The bases would probably be absorbed and finally eliminated in the urine; it was therefore considered advisable to try to find out if normal urine contains one or more pressor substances. Further, it appeared to me to be an interesting problem to ascertain whether in gout, in which a moderately high blood pressure is a fairly common condition, the urine contains pressor materials.

Normal Urine.

I first repeated Abelous's experiments with normal urine; in each experiment two and a half litres of the urine were used. Briefly, the method consists in treating the urine with mercuric perchloride or lead acetate and filtering. The filtrate is freed from mercury or lead in the usual way by sulphuretted hydrogen, again filtered, rendered acid, and evaporated to a small bulk; it is then rendered alkaline with powdered sodium carbonate and extracted with ether; this extract is finally treated with oxalic acid and a minute quantity of an oxalate of the base was thus obtained. This was dissolved in 10 cubic centimetres of normal saline solution, and the intravenous injection of 1 cubic centimetre of this solution was found to cause a distinct rise of blood pressure. (Fig. 1.) Barger and Walpole consider it probable that Abelous's "urohypertensine" is iso-amylamine, but although they evaporated 30 litres of human urine they were unable to obtain sufficient of the base for the purpose of identification. They found, however, that nearly all the pressor action is due to a substance which is volatile with steam, and this would accord with the view that it is iso-amylamine.

I have also found that normal urine contains a pressor

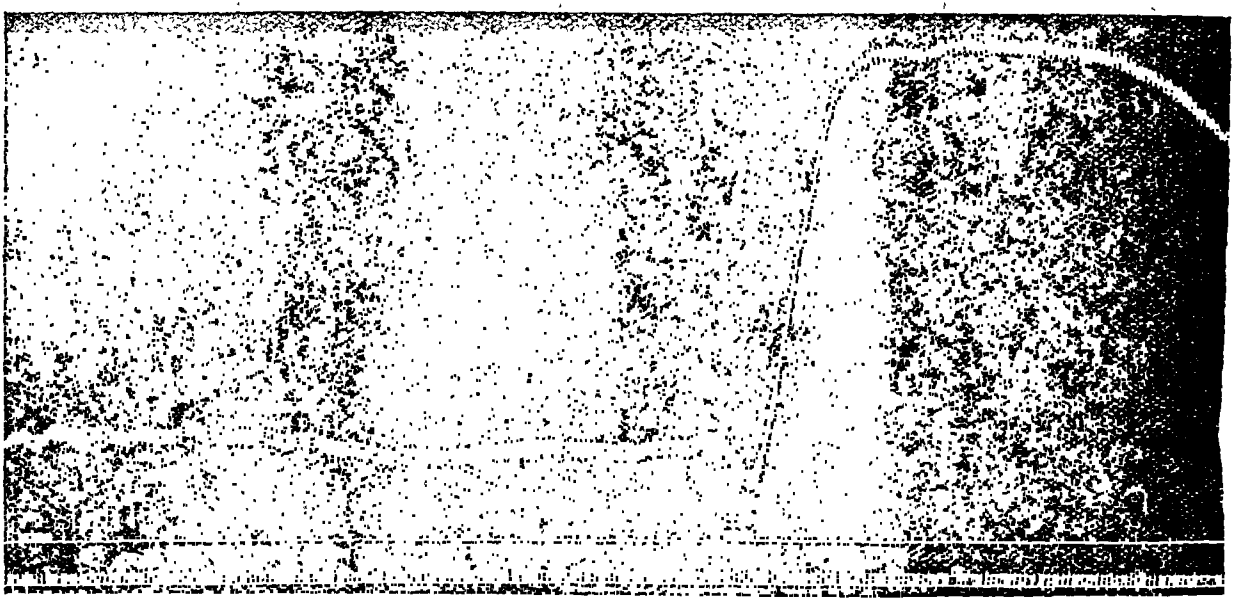
material from gouty urine was injected.

principle volatile with steam. Two and a half litres of urine were acidified, evaporated down to about 15 ounces, and filtered. The filtrate was made alkaline and steam was passed through it. The distillate was extracted with chloroform and the base removed from this solution with dilute hydrochloric acid. The hydrochloric solution was concentrated, first on the water bath and then in a desiccator over soda-lime. The residue was dissolved in 10 cubic centimetres of normal saline solution and neutralised with sodium bicarbonate; 2 cubic centimetres of this solution caused a pronounced rise of blood pressure. (Fig. 2.)

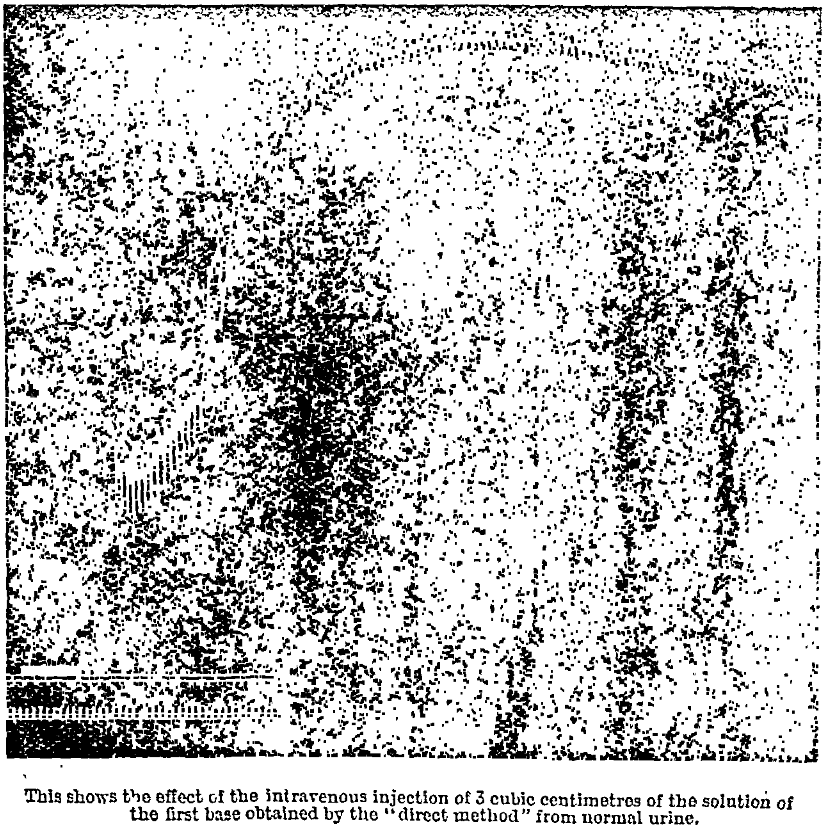
A second pressor base was obtained from the urine after the complete removal of the first base with ether. In these experiments this base was extracted by amylic alcohol from urine rendered alkaline with sodium carbonate. The extract had in every case a distinct pressor effect (Fig. 5) and gave Millon's reaction. It is not improbable that this base is identical with, or nearly allied to, *p*-hydroxyphenylethylamine. Kahlbaum's pyridin-free amylic alcohol was used in these experiments.

FIG. 2.



[illegible] t mark on the signal line 2 cubic centimetres of the solution finally obtained from gouty urine by d. At the second mark 2 cubic centimetres of the solution of the first base obtained by the steam urine were injected. The contrast between the two effects is again most marked.

FIG. 3.



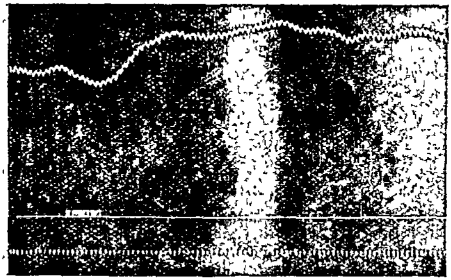
This shows the effect of the intravenous injection of 3 cubic centimetres of the solution of the first base obtained by the "direct method" from normal urine.

In another experiment the urine from which the first base had been removed by steam distillation was acidified and again made alkaline with sodium carbonate, but the material obtained from the amylic alcohol extract only produced a slight rise of pressure; owing to an accident half of the extract was unfortunately lost. It is quite possible that treatment with steam may produce some change in the second base. With the object of preventing, if possible, any change in the bases during their extraction a simpler method was devised. This will be alluded to as the "direct method." Two and a half litres of urine were acidified and extracted several times with ether. The urine was then made alkaline and repeatedly extracted with ether. This extract contained the first pressor base. (Fig. 3.) The urine was again made acid and then rendered alkaline with powdered sodium carbonate and extracted with amylic alcohol. From this extract was obtained the second pressor base. (Fig. 5.) The bases were removed from both the ethereal and amylic alcohol extracts with dilute hydrochloric acid.

Gouty Urine.

The same methods were employed for the investigation of gouty urine. By Abelous's method the first pressor principle was found to be entirely absent in three cases. (Figs. 1 and 2.) These urines contained no albumin. In a fourth case the method by steam distillation was used but the distillate did not contain a pressor substance. A trace of albumin was present in this urine. By the "direct method" the alkaline ethereal extract in two cases yielded a pressor base, but the rise in blood pressure which it caused was much less than that exhibited by similar extracts from the same quantity of normal urine. (Fig. 4.) Amylic alcohol extracted from all the gouty urines the second pressor base, but the rise of pressure produced was not so great as that obtained when normal urine was treated in exactly the same way. Presumably, therefore, the quantity of the second base is less in gouty than in normal urine. (Compare Figs. 5 and 6.)

FIG. 4.



This shows the very slight effect of 2 cubic centimetres of a solution prepared by the "direct method" from gouty urine.

The contrast between the effects with normal and gouty urine is clearly shown in the accompanying tracings, which are selected as typical of the results.

Abelous found "urohypertensine" absent from the urine in a case of arterio-sclerosis. This is the only previously recorded case of a pathological urine having been examined for a pressor substance. In a severe case of interstitial nephritis occurring in a gouty subject I found both bases absent.

These observations are very suggestive, but perhaps it would be unwise at this stage to draw wide sweeping conclusions from them owing to their limited number. The retention or non-elimination of these bases in gout would explain the rise of blood pressure so frequently seen in gouty patients. The influence of diet on the formation of such bases is another question suggested by this investigation.

I have to thank Dr. Rosenheim for his valuable suggestions and help during the investigation. I am also indebted to Professor W. E. Dixon for his assistance with the blood pressure experiments, which were throughout performed on pithed cats. The gouty urines were collected for me by Dr. J. O. Muir, Mr. D. S. Sandiland, Dr. C. Thackray, and Mr. G. G. Butler, to whom my thanks are also due.

Summary.

1. Normal urine contains two bases which produce a rise of blood pressure.

2. The first of these was originally discovered by Abelous and termed by him "urohypertensine." It can be obtained as an oxalate from an ethereal extract of the urine. It is volatile with steam and is probably identical with isoamylamine, a base which is formed from leucine.

3 The second base remains behind after extraction of the first base with ether, and it can then be obtained by extracting with amylic alcohol the urine made alkaline with sodium carbonate. Its reactions indicate that it is identical with, or allied to, *p*-hydroxyphenylethylamine, a base which is formed from tyrosine.

4. Both bases are obtained during the putrefaction of proteins. The existence of pressor basic material during the putrefaction of flesh was discovered by Abelous. The identification of the bases is the result of Rosenheim's work on putrefying placenta and of Barger and Walpole's on putrid meat.

5. Their presence in the urine is explicable on the hypothesis that they are formed by putrefactive processes in the alimentary tract; they are then absorbed and excreted in the urine.

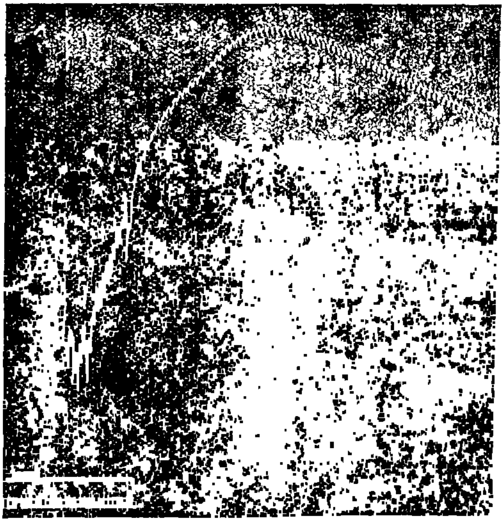
6. In the gouty urines so far examined by the methods of Abelous and steam distillation the first base is entirely absent. By the "direct method," however, a pressor base was present, but the rise in blood pressure caused by it was much less than that produced by a similar extract from normal urine.

The amount of the second base in gouty urine was smaller than in normal urine. The decrease in the elimination of these bases will possibly explain the rise in arterial blood pressure frequently observed in gouty patients.

II.

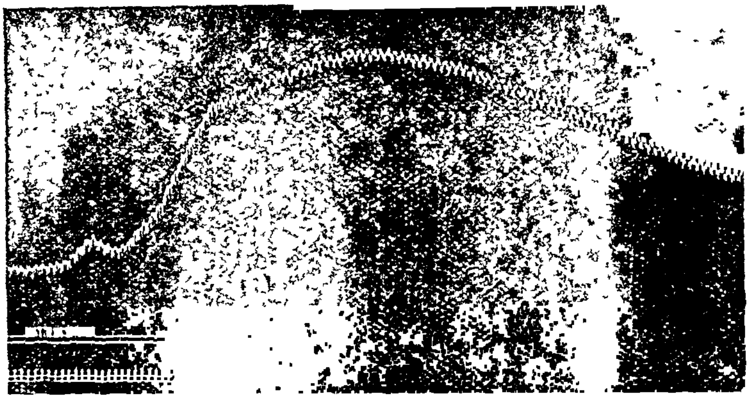
The vulnerability of the kidney in gout is generally admitted, but many cases of this disease run their course without apparently any signs of renal complications. The work of the kidney consists chiefly in the excretion of urea and salts. The functional capacity of the kidney

FIG. 5.



Ef[illegible] the second pressor base (probably [illegible] tained from normal urine by the [illegible] obtained from 2½ litres of urine was [illegible] normal saline solution, and 3 cubic [illegible] at the time indicated on the signal [illegible]

FIG. 6.



An exactly similar experiment with 3 cubic centimetres of the solution obtained from the same quantity of gouty urine. The pressor effect is much less marked than with normal urine.

may be ascertained by estimating the output of chlorides and total nitrogen. It is held that a functional derangement of the kidney may exist without any clinical evidence of renal disease, and that this condition is not uncommon in chronic gout.

The present investigation was undertaken to find out if defective elimination of the urinary chlorides was a feature of chronic gout, and also to ascertain the response of the kidney in gout to an increased amount of work. In renal disease it is well known that the excretion of chlorides is more or less diminished according to the degree and extent of the inflammatory process; therefore in the selection of cases for the purpose of investigation those patients whose urines contained a trace of albumin were excluded.

Clinically, two fairly distinctive types of chronic gout are met with. In the first type the patient has had one or more acute or subacute attacks of the disease, and the so-called uratic deposits are few or absent. The blood pressure is generally more or less above the normal average. In the second type the patient has never had either an acute or subacute attack, and the uratic deposits, which are a distinct feature of this variety, have occurred painlessly. The arterial blood pressure is not infrequently normal, and it may even be somewhat below the normal average level.

The two patients selected for this investigation were about 50 years of age and were admitted into St. George's Union Infirmary, South Kensington, for acute gout, about four weeks before the investigation commenced. They both had had previously several acute attacks of the disease. Their blood pressure was taken in the recumbent posture. A's systolic pressure was 125 mm. Hg; B's 141. The patients were placed upon a fixed diet three days before the urine and fæces were collected. They ascertained beforehand the quantity of the prescribed diet that would satisfy them. A's diet consisted of three pints of milk, four raw eggs, half an ounce of tea in a pint of water, and 36 Huntley and Palmer's breakfast biscuits. B took 42 biscuits, otherwise both diets were exactly alike. This diet was selected as it was comparatively easy to estimate the chlorine content of it. On Feb. 19th and subsequent days 10 grammes of sodium chloride were added to the fixed diet of both patients.

Estimation of Chlorides in the Diet.

The chlorides in the various articles of diet were estimated by Legge Symes's modification of Neumann's method.[5] Briefly, the method is as follows: An ordinary distilling flask is employed with a tapped funnel and delivers through a long adapter to a nitrogen flask (Fresenius pattern) containing $\frac{n}{10}$ silver nitrate. I used a second nitrogen flask in series with the first. 100 cubic centimetres of sulphuric acid and 5 cubic centimetres of nitric acid were used for each gramme of protein. The food material was first inserted into the distilling flask, then the acids were allowed to run slowly in and heat applied; all the chloride is thus evolved as hydrochloric acid. When gas had almost ceased to bubble through the silver solution the tap of the funnel in the distilling flask was opened and the air aspirated through the receiver. The silver solution was titrated with $\frac{n}{10}$ sulphocyanide solution. A sample of the milk was taken daily and the chlorides in 10 cubic centimetres of it estimated. Each egg was weighed and subsequently also its shell. The chlorine content of a weighed portion of two sample eggs was ascertained. The chlorine of the tea, which is very small, was ignored. 12 biscuits were weighed and pounded into a fine powder, and the chlorides in two grammes estimated.

Analyses of the Urine and Fæces.

The chlorides, uric acid, and total nitrogen of the urine were estimated; the latter two partially as a check. The chlorides were estimated by Volhard's method, the uric acid by Hopkins's process, and the total nitrogen by Kjeldahl's method. The fæces were evaporated on a water bath, mixed with alcohol and dried. They were then reduced to a powder and weighed. The chlorine content of two grammes was ascertained by Legge Symes's modification of Neumann's method. The results are tabulated below:—

* On this and following days 10 grammes of sodium chloride were added to the diet.

These results show that in gout the output of chlorides practically balances the intake, and that the kidneys in the two cases under consideration performed their work in a satisfactory manner—in fact, behaved as normal organs.

There are two significant points to be noted in the tables. On Feb. 18th in the case of A there appears to be a simultaneous retention of uric acid and total nitrogen. This combination has not been observed before, but little or no importance can be attached to an isolated experimental observation. Attention may also be drawn to the very pronounced difference in the output of uric acid in the two cases, both practically on the same diet.

It was thought of interest to determine the amount of chlorides excreted during the administration of an excessive quantity of common salt in the diet. A gouty patient was asked to take as much chloride of sodium with his food as he conveniently could, and after a couple of days the 24 hours urine was collected for three days in succession. A similar experiment was carried out with a case of chronic nephritis and the results are presented in tabular form.

TABLE V.—*Showing the Excretion of Chlorides and Urea in the 24 Hours.*

in both, and one sees in
retention of chlorides in
with the gout case.[6]

It has been suggested that mineral waters containing sodium chloride should not be given to gouty patients unless the sodium chloride content is minimal. The argument used to support this suggestion was that in gout every kidney was potentially a diseased organ and that in nephritis a retention of chlorides occurred. The natural mineral water containing sodium chloride with which I am most familiar acts both as a purgative and a diuretic. As this water quickly passes through the alimentary canal most of the salt is eliminated in the fæces, and the small extra amount with which the kidney has to deal appears to have a stimulating effect upon that organ, and, as these experiments show, cannot be regarded as harmful, seeing how readily the kidney in cases of gout excretes much larger amounts added to the food. When there is evidence of kidney disease it is obvious that such waters must be cautiously prescribed.

Attention has been drawn in the first part of this paper to the diminished excretion of the pressor bases in cases of chronic gout. If these bases are retained it can scarcely be due to the incapacity of the kidney to eliminate them, for we know that separating the salts from the blood is the hardest work the kidney has to perform, and we have seen that in two cases of gout this task the kidney adequately accomplished.

I have to thank Dr. Muir for placing the two patients at my disposal and for the care which he took in seeing that the experimental requirements were complied with. I am also indebted to Mr. Sandiland for collecting the urines of the other two cases for me.

Harrogate.

THE RELATIVE TOXICITY OF CHLOROFORM ($CHCl_3$) AND OF CARBON TETRACHLORIDE (CCl_4).

BY AUGUSTUS D. WALLER, M.D., F.R.S.,
DIRECTOR OF THE PHYSIOLOGICAL LABORATORY OF THE UNIVERSITY OF LONDON.

With a Note on the Danger of Carbon Tetrachloride as a Dry Shampoo by V. H VELEY, D.SC., F.R.S.

THE recent sad death of a young lady under the hands of a hair-dresser while her hair was being treated with a dry shampoo containing carbon tetrachloride has brought to my mind experiments that I made many years ago on the toxicity of chloroform and of carbon tetrachloride as measured by their physiological action upon isolated nerve. I have pursued experiments of the same kind during the last year by a more convenient and expeditious method, in which isolated muscle is used as the indicator, and which affords comparative data from which it is possible to assign a numerical value to the physiological power of anæsthetic and other toxic reagents.

Taking as a standard of reference the toxicity of ordinary ethyl alcohol in a solution of molecular strength (4·6 grammes per 100, i.e., a percentage approximately that of light wines and beers) I find as its physiological equivalent a centimolecular solution of chloroform—i.e., that molecule for molecule chloroform is 100 times as toxic as ethyl alcohol.[1]

Taking now as my term of comparison the toxicity of chloroform at the three strengths m/400, m/200, and m/100 (= 0·3, 0·6, and 1·2 grammes per litre) I find that the toxicity of carbon tetrachloride is considerably greater than that of chloroform at the same three molecular strengths m/400, m/200, and m/100 (= 0·375, 0·75, and 1·5 grammes per litre).

Finally, taking the incriminated hair-wash—which principally consists of carbon tetrachloride—in the same three percentages (0·375, 0·75, and 1·5 grammes per litre) I find that the toxicity of hair-wash is considerably greater than that of carbon tetrachloride at the same three percentages.

I give herewith illustrative records of the comparative effects upon isolated muscle of the three reagents in question —chloroform, carbon tetrachloride, and "hair-wash"—under similar conditions of experiment. To anyone who might be inclined to doubt the cogency of such experiment I would observe that while obviously this test upon muscle does not reveal what strengths of the reagents in question are lethal to the human subject, it does reveal clearly what are their relative toxicities. No one doubts that it would be inconvenient or dangerous to envelop the head in a cloud of chloroform vapour; *a fortiori* it is inconvenient or dangerous to envelop the head in a cloud of carbon tetrachloride vapour; and finally the incriminated hair-wash, of which I am informed many tons have been used by one firm alone, is more poisonous even than pure carbon tetrachloride, and therefore more dangerous still.

Chloroform, as is well known, is a reagent of great toxicity—according to my observations 100 times that of ethyl alcohol. Carbon tetrachloride has, I judge, a toxicity about double that of chloroform. Hair-wash, of which the principal ingredient is carbon tetrachloride, has a still greater toxicity, but the experiments which I have made on this material are not sufficiently numerous to permit me to give a numerical estimate, nor am I able to say what may be the additional substance or substances present in the wash to which that greater toxicity may be due.[2] In any case the carbon tetrachloride present in the wash is, in my opinion, sufficient to cause the death of a healthy person apart from any question of fatty heart or adenoids or status lymphaticus. The cloud of heavy vapour by which the head might be enveloped would necessarily be more or less abundantly inspired, and a very few inspirations of such a highly poisonous vapour would suffice to cause drowsiness or sleep, and might be expected sooner or later actually to cause death.

The Danger of Carbon Tetrachloride as a Dry Shampoo,
by Dr. V. H. VELEY.

The recent fatal accident under the hands of a hairdresser has called public attention to the above matter, and it is stated that at least one other death as well as several cases of faintness have occurred previously. The compound carbon tetrachloride (CCl_4) has in recent years been introduced as a solvent for fats, partly from improvements in its manufacture on a large scale, and partly because it possesses advantages over carbon disulphide and benzine or petrol in that its odour is not very disagreeable and the mixture of its vapour and air is not inflammable.[3] The compound has been introduced into laundries and the hairdressers' trade mainly for ladies who desire to save the time of drying off water. A sample of liquid used for the latter purpose was obtained from a well-known firm for examination in the laboratory of the University of London. Its effect on isolated muscle is described above by Dr. Waller. It was considered that it might be of interest if an approximate chemical analysis was also made.

The liquid was slightly milky; its density at 15·5° C., as compared with water at the same temperature, was 1·5963. It was fractionally distilled by means of a Young's evaporator still-head with three bulbs and gave the following fractions boiling at a barometric pressure of 755 millimetres:—

Portion below 60° C.	= 1	per cent.	(mainly carbon bisulphide).
,, between 60–76° C.	= 5	,,	(mainly carbon tetrachloride).
,, between 76–77° C.	= 88	,,	(carbon tetrachloride).
,, above 77° C.	= 4	,,	(water with scented matter).
Loss	= 2	,,	
	100		

The density of the main bulk of liquid boiling at 76–77° at 15·5° C. was 1·6024. Thorpe[4] gives the boiling point of pure and well-dried carbon tetrachloride as 76·5° C. at barometric pressure 754·3 millimetres, and its density at 0° C., compared with water at the same temperature, as 1·63216, which would correspond to a density of 1·6045 at 15·5° C. The main portion of the distillate was nearly pure carbon tetrachloride. The probable approximate composition of the liquid examined is: carbon tetrachloride, 94 per cent.; water with scent, 4·5 per cent.; and carbon disulphide, 1·5 per cent. (derived from manufacture). A liquid of the above composition would have a density at 15·5° C. of 1·583, which is approximately equal to that found. The carbon disulphide, although present in only small amounts, is itself intensely poisonous and quite sufficient to increase the toxic effect of the hair wash as compared with that of carbon tetrachloride by itself, as appears from Dr. Waller's records. It must further be considered that the vapour of carbon tetrachloride is in round figures 5·3 times heavier than air, so that, notwithstanding any fanning, this vapour, which is considerably more toxic than chloroform vapour, must fall over the face of the person operated upon, and consequently be inhaled.

It is not a matter of surprise that fatal cases should occur and it appears to be most desirable that the legislature should prevent such operations for hair-dressing, as also the use of carbon tetrachloride in laundries except in some closed vessel. A suitable Bill, or an amendment to existing Acts, could hardly be regarded as contentious and might be passed by both Houses of Parliament in a short time as a matter of public urgency.

MEDICAL RELIEF AND PUBLIC ASSISTANCE.[1]

BY C. S. LOCH.

THE report of the council of the Poor-law Medical Officers' Association for 1908–09 may be taken, I think, as the text of this paper. It raises some questions which are questions preliminary to the discussion of administrative changes in regard to the work of district medical officers, and on these its pronouncements may, I presume, be taken as final for the purposes of this meeting. To do this will give point and pertinence to the discussion.

I conclude from the resolutions carried by the council[2]:

1. That the council of the Association are not in favour of free medical relief. In opposing a proposal with which I shall deal hereafter—namely, "to make every medical practitioner a Poor-law medical officer"—they expressed the opinion that such a proposal "would largely tend to provide free medical relief to all poor persons, and to increase rather than diminish the pauperisation of the nation." The council are

thus opposed to any system that would tend to the provision of free medical relief to all poor persons. 2. I conclude also from the latter part of the sentence I have quoted and other phrases that the cour[illegible] pauperisation that m[illegible] those who are under [illegible] it. They wish to diminish pauperism. 3. Lastly, I conclude that by the statement, "That the interests of the sick State poor would be far better attended to by a special service, the members of which are adequately paid, and whose work was capable of proper inspection," the council refer to a modification of the present system of medical poor relief and do not have in view a new organisation of public health and sanitation *plus* medical relief, which some have suggested. The wording of Resolution (4) as a whole suggests this interpretation. The proposal in question has, no doubt, come before the council. But judging from the silence of the report, I conclude that they do not raise that issue. Accordingly, from the point of view of this discussion I pass it by.

Leaving, then, these preliminary questions, I would state shortly the purport of the report of the Majority of the Royal Commission on medical relief. The Commission aimed at improvement on four points: (1) they desired a more efficient system of public medical assistance; (2) they desired to bring the agencies for the supply of medical relief into some kind of coördination; (3) they wished to prevent any undue deterrence being attached to applications for medical relief; and (4) they desired to promote independence and contributory and provident methods of obtaining advice and treatment.

As to efficiency, what was amiss? The provision of indoor medical relief was often defective, especially in rural [illegible] which was in receipt of outdoor relief was often very insufficient. This is a major cause of dissatisfaction. All outdoor relief should, it was felt, be conditional and provided under close supervision and subject to the fulfilment of all necessary requirements of cleanliness and sanitation. In the case of indoor relief persons suffering from some diseases were allowed to go out of an institution quite improperly. For the sake of the protection of the people at large they should be deprived of their liberty until they were cured. Thus children suffering from ophthalmia should not be allowed to leave with their parents. There was insufficient inspection on the part of the Local Government Board and there was no inspection by any local authority. On boards of guardians there was usually no member who was a medical man and qualified to advise on medical questions or to criticise. There had been a great advance in the supply and organisation of medical relief in urban districts, but much remained to be done. For this and for a better administration generally it was recommended that there should be in each county and county borough, a Public Assistance Authority which should definitely undertake the duties of the supply of medical assistance for the county or county borough, promote an organisation of public and voluntary medical agencies, and meet defects that had come to light. This Public Assistance Authority might appoint a medical assistance committee to undertake this branch of work.

As to deterrence, it seems that the Poor-law infirmaries and medical out-door relief deter less and less, particularly as institutional medical relief becomes dissociated from the workhouse. The deterrence of the franchise should, it is suggested, be withdrawn absolutely. No parent would lose his vote by reason of medical attendance provided for his wife or child. Medical relief is often, it is said, the first step to pauperism. On this generalisation some doubt is thrown, at least in regard to its effect as generally administered. The word "destitution" in the sense in which it is used in relation to the able-bodied, a state approximate to starvation owing to a lack of the necessaries of life, has already by usage assumed a far less stringent meaning in the case of medical relief. It has "come to mean no more than this—viz., inability to provide whatever medical treatment is necessary." As Dr. Downes has remarked to us: "The Poor-law, therefore, has been obliged to provide for the sick on a scale continually advancing with the standard of the care of the sick, and as, with medical progress, this provision becomes more complete, the more unequal in the absence of effective organisation, is the condition of the man who tries to provide it for himself." Another deterrent, it is said, is the application to the relieving officer instead of the district medical officer. This is to be no longer insisted upon. The applicant might go to the district medical officer direct.

So the Commission, having modified, indeed removed, the condition of deterrence very largely, suggest an alternative and submit a plan of promoting an effective organisation to enforce what one may call self-deterrence to enable those who will to provide medical treatment for themselves. They propose that the power of recovering the cost of medical relief should be used in the case of persons who could have afforded to join a provident dispensary and have not done so. They propose also that in these cases investigation should be made—a process that might be set aside in the case of members of a provident dispensary who have a proper wage-limit. Further, they recommend the promotion of provident dispensaries by the Public Assistance Authority on the understanding that "the British Medical Association should suggest a general scheme or scale of fees and wage-limit to be applied by minor local branches as local circumstances may suggest." Agreements would be made with voluntary hospitals for the treatment of special cases in them. The member of the provident dispensary would be allowed to choose his own medical attendant, and through his dispensary doctor might be assured admission to a voluntary or general hospital in certain cases. In fact, generally, the principle is advocated that those who can pay towards their treatment should do so according to their ability, and that for those who have not the means to pay the Public Assistance Authority should pay.

It may be said: "What has this to do with invalid children?" The answer really is: "Everything." If the scheme is adopted, the portal of the provident dispensary or sick club would open the way to them for constant and sufficient medical treatment.

The policy of the report is the careful treatment of the individual case. This policy should be applied to this department of work as well as to others. There would be nothing to deter the parent from seeking medical treatment for the child, for instance. But if he did not belong to a provident dispensary his circumstances would be investigated and he would have to pay if possible. Associated action should prevent failure, whether the child be taken to a voluntary hospital or to a Public Assistance officer. This in abstract is the scheme.

The objections to these proposals formulated by the council are four. I may paraphrase them as follows:—

1. Poor-law medical relief cannot be placed on a provident basis. That relief is for those who cannot contribute, and for no others. But provident methods imply ability to contribute.

2. Not only so, but the plan would be bad for provident institutions. The number of those who apply for Poor-law medical relief is large. If they were treated as members of provident dispensaries, they would flood the dispensaries. The dispensaries supported out of the poor-rates to so large an extent would become Poor-law institutions. The better provident dispensary members would desert them. The poorer dispensary members who remained would be fused with the Poor-law members, and the number of persons dependent on the Poor-law would increase accordingly. We should end by becoming not provident but pauper dispensaries. The State poor would oust the independent members.

3. This would be more expensive. It would mean free medical relief to all poor persons. The work of the medical officer would be of such a mixed character that it could not be inspected properly or tested properly.

4. Applications should, as at present, be made through the relieving officer. This prevents pauperism and removes from the district medical officers a duty which does not, strictly speaking, come within their province.

One sentence I omitted. It is: "That the interests of the sick State poor would be far better attended to by a special service, the members of which were adequately paid, and whose work was capable of supervision." I omitted this because it seemed to me to convey in a great degree what the Commission recommended.

In their scheme[3] Public Assistance takes the place of Poor-law, a change that implies a difference of method. The Public Assistance Authority (or the Medical Assistance Committee) of the county or county borough deals with the large area of the county or county borough. It organises arrangements and makes appointments for districts corresponding to unions in that area. The district medical officers become members of a county service, and indirectly of a State service. "Indirectly" because they are not actually paid by the State but by the county. The obligations imposed on them remain as at present, subject to changes to their advantage which the Commission suggest. But it is suggested by the Commission that parallel to this medical assistance of the Public Assistance Authority, and unavoidably related to it, there must be an organisation of medical relief which will make such relief more effectual, and will also, as far as may be, be so administered as to prevent dependence.

From the point of view of this discussion we may consider that there are two groups. One consists of the members of provident dispensaries and societies and sick clubs; the other consists of the applicants for public (or Poor-law) medical assistance. The problem is how to make medical aid more effectual and at the same time to prevent those who would be inclined to gravitate to public relief adopt some alternative course that would prevent this; and *vice versâ*, to push in to the provident and preventive circle any who might be so assisted. To do this, it is clear the advantages to be obtained by those who provide for themselves in sickness should not be less than those obtainable by outsiders, that is, by those who make no such provision. Sickness is sickness, and in either case has to be cured or relieved. Hence, for instance, the members of the dispensaries should certainly have at least as great advantages by way of special treatment at hospitals or elsewhere as the State system provides for those who apply to it. This is not always so now. But it is made possible by the removal of deterrence on the one hand, and on the other hand by the gradual establishment of a single coöperative medical system throughout the country. Instead of the deterring from free medical relief, the system supports and promotes the method of provident provision, so that it may be more attractive and more advantageous than free relief. Instead of increasing to a greater and greater extent institutions available technically for the pauper only, it gives the provident the advantage of these institutions. The administration of medical relief is no longer cut up into blocks. It becomes in a manner unified, so it is hoped, through the action of the new organising force which is represented by the Public Assistance Authority or the Medical Assistance Committee.

But it is not proposed to merge provident dispensaries and sick clubs in the "Poor-law." District medical officers will not become the officers of "Poor-law" provident dispensaries, if I may so put it. The provident system will be, as it is now, independent of the Poor-law or Public Assistance. Only the Public Assistance Authority, acting on behalf of the community at large, will "play up" to the dispensaries. There will be no large or off-hand transfer of cases to provident dispensaries or sick clubs from the committees of Public Assistance. If among their cases are young people and others who can suitably become members, they will, if possible, be drawn into membership of the provident dispensaries. Roughly, I suppose the division that is actually in force would continue, at least for some time. Chronic patients would tend to go to the Public Assistance officers and institutions, and patients suffering from acute illness would pass to the hospitals. But the division of responsibility would have to be settled according to local conditions. It would appear from this that the objections of the council rest on a misunderstanding. "Poor-law medical relief cannot be placed on a provident basis." Granted. What is proposed is "that medical assistance should be placed on a provident basis"—that is, that the new organisation of the Committee for Medical Assistance, which would deal with various kinds of institutions and agencies, voluntary and other, should have that as its object. Accordingly, in my judgment, the first objection disappears. Next, it is not proposed that the provident dispensaries should be flooded with the chronic (or other) sick poor who seek public relief. Provident dispensaries will continue as they now do. Only the influence of the local medical men and the laity interested directly or indirectly in these institutions would be exercised to promote them on the principle that those who can pay should pay—a principle amply suported by the evidence taken by the Commission. Therefore the evils referred to in the second of these objections would not occur, so far as one can at all foresee what would take place. The objection as to expense also drops. Every man who passes into the "provident" range is putting himself to more expense by his provident payments, but his country he is prospectively putting to less expense.

Lastly, comes the question of the introduction of the relieving officer. The suggestion is made to meet a criticism of the present administration. So far as the provident system supersedes that of the medical relief, the application would be made to the dispensary doctor whom the applicant selects; so far as it does not, some suitable arrangement would have to be made for the non-medical side of the work, the inquiries that have to be made, &c. The object is to avoid what may cause any deterrence, which is wrong or injurious in sickness.

If the scheme of the Commission is put in force and succeeds there will be a constant upmoving of the applicants to the provident or paying range. If we can realise a state of society in which this process is complete, undoubtedly the district medical officers would have no work to do—at least in that capacity. In my opinion, a very large section of the population who now are treated gratuitously could pay towards their treatment, and improvement in this direction would affect the number of persons applying to the Public Assistance Committees in some districts very greatly. But this prospect of district medical officers thrown out of work is, I think—or should I say, I fear?—rather visionary, at any rate in our urban and more populous districts. It is enough if at present we establish a public organisation which will create a good public method of intimate coöperation between the medical profession and the agencies concerned in the care of the sick, and in so doing will promote effectual medical assistance and independence.

AMELIORATIVE MEASURES INDICATED BY SCHOOL MEDICAL INSPECTION.[1]

BY JAMES ROBERT KAYE, M.B., D.P.H. CAMB., F.C.S.,
MEDICAL OFFICER TO THE WEST RIDING COUNTY COUNCIL.

THE question of amelioration is the logical sequence of School medical inspection, and the value of the latter may be regarded as proportionate to the success obtained in remedying the defects discovered. If that is so, then the value of medical inspection will be enhanced in proportion to the comprehensiveness of the scheme in use. School medical inspection indicates the conditions affecting, or influencing, the physical and mental aspects of the scholar, whether healthy or ailing. It should have regard to the premises and their condition; to the methods of teaching in relation to the capacity of the child; to the early detection of unsuspected defects; to the school as a factor in the dissemination of communicable diseases; in short, to the securing of all those conditions of school life best calculated to produce the full and effective physical and mental development of the child. It is not a scheme for the compilation of statistics and anthropometric measurements, nor can any such system be regarded as a sound basis for medical inspection.

It is not my intention to discuss these very interesting items. I prefer to confine my few remarks to the means which may be employed to forward the amelioration or removal of the defects revealed by inspection. In a broad sense, then, amelioration means the process of improving existing conditions, and so in some measure it may be regarded as synonymous with treatment, while at the same time it is associated and bound up with the question of prevention. It is our desire to utilise amelioration in its widest sense, in not being restricted to defects only, but as being concerned also with the improvement of all conditions promoting healthy living in the school period, and with the ultimate object of racial betterment. I assume there can be no objection raised to any attempt to remove faulty and defective physical and mental conditions, and, in fact, we marvel at our apathy in not dealing with this most important question ere now.

---

[3] Our main proposals for medical assistance are as follows: The primary responsibility of the Public Assistance Authorities for the inspection and supervision of medical assistance should be clearly recognised and carefully maintained, but meanwhile the arrangements for both indoor and outdoor medical assistance should be periodically inspected by medical inspectors on behalf of the Local Government Board; to this end the Board's staff of medical inspectors should be increased. That the Public Assistance Authority, to assist them in carrying out their functions in connexion with medical assistance, shall [illegible] ch shall be added [illegible] ity council or of [illegible] r branches of the [illegible] alled the County [illegible] the case may be, [illegible] ospitals, county [illegible] and registered friendly societies.

[1] A paper read at the Health Congress at Leeds on July 19th, 1909.

The school population of England and Wales is estimated to be about 6,000,000, and, according to the revelations disclosed by inspections already undertaken, there cannot be at the lowest computation less than 4,800,000 children in our elementary schools who cannot be described as sound in body and mind, and amazingly enough these infirmities are largely removeable if dealt with sufficiently early, and are even preventable. Presumably many of these children will continue to be hampered in their educational progress unless some facilities of relief are afforded. This assertion does not require to be supported by figures or statistics; the past history is enough, and there is the inference that many adults now are suffering from ailments which have originated in school life. Such a remark refers largely to defective hearing and vision, and imperfect bodily formation. It is true that already medical inspection and the consequent remedial work are removing the reproach upon our educational system of the lack of appreciation of the interdependence of the mind and the body, and of the fact so long overlooked that schools are places where human beings are developed—because in its broader aspects school hygiene is indeed an integral factor in the health of the nation.

The Circular 576 issued by the Board of Education in November, 1907, under the powers of the Education (Administrative Provisions) Act ("the Children's Charter"), urges upon the local education authorities in no half-hearted way the desirability of formulating a scheme of amelioration, so that medical inspection will be something more than a mere record of disabilities and defects. Local education authorities have been empowered to make arrangements for attending to the health and physical conditions of the children. It may be here pointed out that already practical amelioration or modification has been in progress in the mode of instruction, particularly of the infant, in the nature and extent of the work, and its distribution in the time-table, in the use of physical exercises, and in the prevention of infectious diseases. It is also admissible to refer to the improvements in the provision of ventilation and lighting, and the placing of those defective or impaired in sight and hearing under more favourable conditions in school. Further, special legislation has provided treatment for the blind and deaf, the epileptic, and the mentally and physically defectives, while the necessitous and poorly nourished have been cared for by the Education (Provision of Meals) Act, passed in 1906.

The principle of amelioration has therefore been fully recognised, and now comes the difficulty of finding the best method of extending this ameliorative treatment to meet the present situation. In attempting to evolve some scheme of amelioration it is necessary at the outset to realise the character of the different diseases attacking scholars. The source of our trouble is not with acute diseases like pneumonia, or even infectious diseases, because these receive due consideration and treatment, nor is it the minor accidents or bruises, but it is a class of affections and diseases more or less chronic in character, such as the parasitic and contagious, dental conditions, defective vision, affections of the eye, ear, and nose, and neglected conditions arising from infantile paralysis and rickets. Due regard must also be taken of the character of the district, because measures which may be applicable to an urban and concentrated population are impracticable in a rural and sparsely populated area.

Reference may here be made to the conduct of the parents in relation to the minor ailments, often erroneously so called. It is in regard to these that many parents often seem most apathetic and careless. Fortunately this neglect is not universal, and even a large proportion of it is due to ignorance or poverty. Apart from ignorance, we must bear in mind the difficulty, the trouble, the inaccessibility of institutional treatment, and the chronicity of the ailment, all helping to engender neglect in the parent.

The importance of prompt remedy, more especially of eye and ear defects, cannot be overestimated, yet it is with these main avenues of knowledge that difficulty is mostly experienced. It is sad to think how much a child with such defects misses simply for want of some attention, besides the leakage of effort on the part of the teacher and the corresponding wastage of public money. Fortunately, we have the definition that attendance is not an attendance in law unless the child is in a fit condition to attend school. Further, we are fortified by the Children Act, 1908 (Section 12), which we welcome, by which penalties may be inflicted on a parent or guardian who refuses to obtain treatment for the defective eyesight or hearing of his child, while Section 122 empowers the school medical officer to remove the verminous affected child for cleansing under certain conditions.

At present, immediately after the school inspection, notice is sent to the parent that his child is suffering from some defective condition requiring medical attention, and children suffering from infectious or contagious or parasitic affections are excluded from school. As yet no prosecution has followed these exclusions for absence from school, but it has been considered in several instances. Other measures have been discussed: subsidy to hospitals and dispensaries, to dentists and Poor-law medical officers, and the establishment of school clinics. These have their advantages, but in an area like the West Riding of Yorkshire the disadvantages preponderate. It might be thought advisable to utilise the district nurse and sundry local agencies, but as the result of an anxious search for a practical and possible scheme it was thought that the interests of the defective child would be best served by the utilisation of the district subcommittees and of local philanthropic help in the formation of "care of children committees." Such a committee would be practically the district education subcommittee, with the addition of special workers if necessary, who would report as to the condition of the individual child entrusted to their care and supervision at the monthly meetings of the district subcommittee and continue to report until the visitor was satisfied or otherwise with the result.

To put it briefly, the aims of these committees by means of home visiting might be set out as follows: 1. To help the parents to grasp the aims and objects of medical inspection, which is, indeed, the welfare of each child. 2. To impress upon parents the gravity of permitting the continuance of defects which in later life so seriously handicap the sufferer and limit his scope of usefulness. 3. To encourage the improvement of home conditions where necessary. 4. To afford proper advice and guidance. Much money is wasted on ill-advised and useless methods of treatment. 5. To help poor cases deserving local philanthropy. 6. To maintain an interest in cases requiring constant attention and treatment over lengthened periods. 7. To secure the utilisation of local agencies, such as district nurse, guilds of help, charitable organisations, surgical aid societies, and hospitals. 8 To keep an eye on mental and physical defectives, and to indicate a suitable course of action. 9. To report, or call the attention of the proper authority to, any cases not receiving consideration. 10. To impress upon parents the desirable dignity of responsibility in dealing with those diseases in their children within their means; in fact, the duty of doing everything possible for the welfare of their children. 11. To inaugurate and establish a crusade of prevention, on the principle that prevention is better than cure, and that many of the ailments of children are preventable. 12. To accentuate the interest of the members of the district subcommittees in the struggle for racial improvement.

In such ways we may expect a healthier and happier race [illegible] hope of a [illegible] ife by un- [illegible] *Besides,* there is the expectation of raising the general level of know- [illegible] curtailing [illegible] employed, [illegible]

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Non-ovarian Pelvic Dermoid Tumour.—President's Valedictory Address.

A MEETING of this section was held on July 8th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Miss M. H. FRANCES IVENS, M.S., read a short communication on a case of Non-ovarian Pelvic Dermoid Tumour. She pointed out that dermoid tumours originating in the pelvic connective tissue, non-ovarian in origin, were apparently of infrequent occurrence, and that she had only been able to collect 29 reported cases. Gebhard, when commenting on the rarity of these tumours, pointed out their tendency to be of a somewhat simpler structure than the highly complex ovarian dermoids, hair and teeth being of infrequent occurrence. Their origin was uncertain, and symptoms, when present, had been chiefly due to pressure on adjacent pelvic organs. Repeated attacks of pelvic inflammation had usually occurred. The case recorded was that of a married woman, aged 26 years, nulliparous, who was admitted to the Liverpool Stanley Hospital complaining of severe pelvic pain. It caused her great pain to sit down, and also during defæcation; she had suffered, but to a less degree, from attacks of a similar nature during the past seven years. A fixed, tender, fluctuating swelling of the size of a goose's egg was felt high up in the left fornix, and was thought to be a pyosalpinx or ovarian abscess. A few days later some substance, like thick matter, was said to have been passed per rectum. Laparotomy was performed and the tumour was then found to be beneath the peritoneum and in front of the rectum and to have no connexion with the uterus or appendages. The peritoneum over it was incised and the tumour shelled out and removed entire. No drainage was employed. On examination of the cyst it was found to contain a buttery material of an apple-green colour and very offensive odour, and the cyst wall, which was thick, presented at one point a softened area where it probably had intermittently communicated with the rectum. The cyst was lined with granulation tissue, from which all traces of epithelium had disappeared. The patient, who exhibited some alarming symptoms indicative of toxæmia for the first few days, ultimately recovered and left the hospital well.—Dr. G. E. HERMAN said that he had, in a lecture published in the *Clinical Journal* of August 22nd, 1900, p 277, recorded a case of a pelvic dermoid (not ovarian) which suppurated whilst the patient was recovering from an uncomplicated ovariotomy. In a paper on the Suppuration and Discharge into Mucous Cavities of Pelvic Dermoid Cysts (published in the Transactions of the Obstetrical Society of London, Vol. XXVII., 1885, p. 254) he had collected a number of cases, some of which he thought were certainly not ovarian.—Mr. ALBAN DORAN desired to know Miss Ivens's opinion about the origin of the dermoid. It was not probable that the dermoid elements arose from displaced ovarian tissue, but it seemed very likely to be the homologue of the dermoid cysts occasionally found in the abdomen of men, as in Ord's case recorded in Vol. XLIII. of the Transactions of the Royal Medical and Chirurgical Society, where the tumour was closely related to the bladder and rectum.—Dr. F. H. CHAMPNEYS said that he had seen one similar case. The tumour lay between Douglas's pouch and the sacrum, was about the size of an orange, and had no apparent connexion with either ovary. It came into notice first during labour, caused considerable obstruction, and the patient died from sepsis.—The PRESIDENT asked whether it was possible that the tumour was a degenerated fibroid. He had met with a case in which he had enucleated a tumour per vaginam from Douglas's pouch. The pultaceous contents led him to think it was a dermoid. He had to open the abdomen for oozing, and found that it was a fibroid which had grown from the back of the lower segment. Examination of the tumour with the microscope showed it to be a cystic fibro-myoma. He had several times observed the solidification of the contents of degenerated fibroids (from clotting), and this he thought might be mistaken for the setting of the liquid fat of a dermoid.—Miss IVENS regretted that she had not seen the paper by Dr. Herman on the Suppuration and Discharge into Mucous Cavities of Dermoid Cysts of the Pelvis, and mentioned that her communication referred entirely to retroperitoneal dermoids. In answer to Mr. Doran's question respecting the origin of the cyst, Miss Ivens said she believed it to be derived from fœtal remnants, probably the post-anal gut or projection of the hind gut behind the proctodeal depression. Replying to the President that no hair or skin lining could be seen, she said that the diagnosis rested on the greasy character of the contents, which though liquid on removal solidified to the consistency of butter on cooling. After repeated attacks of suppuration extending over a period of seven years it was unlikely that the original lining of the cyst could be demonstrated.

The PRESIDENT then delivered a valedictory address to mark the close of his term of office as President of the section.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Annual Meeting.—Exhibition of Cases.—Symmetry and Asymmetry and their Effect in the Production of Lateral Curvature of the Spine.—Observations concerning the Blood in Chorea and Rheumatism.—Multiple Abscesses of the Liver.—Etiology and Treatment of Hyperpyrexia in Childhood.—Acute Leucocythæmia.—Treatment of Irreducible Intussusception by Lateral Anastomosis.—Primary Source of Infection of Glands in the Neck.

THE annual meeting of this section was held at Edinburgh on June 18th. The members of the section were received with cordial hospitality by the profession in Edinburgh and were entertained to lunch before the meetings. At the meeting in the afternoon there was first a discussion of cases. Tea was then served, after which papers were read. The official proceedings terminated with a very enjoyable dinner in the evening. On the following day a number of extremely interesting cases were shown at the Edinburgh Royal Hospital for Sick Children to those members who remained in Edinburgh.

At the afternoon meeting Dr. GEORGE CARPENTER, chairman of council, presiding, Dr. G. A. GIBSON showed a case of Patent Ductus Arteriosus in a young woman.—Dr. CARPENTER said that it was seldom such cases were seen clinically. In this condition there might be a purely systolic murmur and not a double murmur. He suggested that an X ray photograph should be taken of the case, as it had been shown that dilatation of the pulmonary artery could be recognised by this means. The malady was not infrequently associated with other congenital malformations.

Dr. JAMES BURNET showed a case of Delayed Rickets.—Dr. G. A. SUTHERLAND asked if the rickets had developed recently or if the condition had persisted from infancy.—Mr. A. H. TUBBY thought that rickets was a disorder beginning in childhood and continuing with outbreaks at intervals afterwards, the causes of which are unknown.—Dr. E. I. SPRIGGS referred to recent work on exercise as a cause of rickets.—Dr. C. J. MACALISTER, Mr. HAROLD J. STILES, and Dr. CARPENTER also discussed the case.

Mr. E. W. SCOTT CARMICHAEL showed a case of Deformity of the Cervical Spine and the Right Scapula in which there was a fold of skin at the side of the neck reaching from the head to the shoulder.—Mr. TUBBY said that it was one of those curious cases known as Sprengel's shoulder. The right scapula differed in shape from the left. The movements of the shoulder were limited. He also suspected the presence of supernumerary cervical ribs. The skin folds, which he had not seen before, showed, he thought, the traction of the skin in the attempted descent of the scapula.—Dr. CARPENTER asked if there were any other deformities, and Mr. TUBBY said that in about one-third of the cases congenital heart disease was associated.

Mr. STILES showed a case after Cholecystenterostomy for Traumatic Obstruction of the Common Bile-duct.—Dr. CARPENTER suggested that as this case had been so successful congenital malformations of the bile-duct could probably be treated surgically.—Dr. JOHN THOMSON said that such cases had been operated on, but the result had always proved that the operation could not possibly have been expected to do good, as it was not a local condition but general disease.—Dr. SPRIGGS suggested that metabolic observations should be carried out in this case as the bile ran straight into the large intestine, and it would be interesting to see how the splitting and absorption of fats were affected by the absence of bile from the small intestine in man.—Mr. HUGH LETT referred to a case of traumatic obstruction of the bile duct which recovered.—Dr. CARPENTER said that operation might be successful in congenital cases in which the stenosis was merely related to the common duct.

Mr. STILES also showed two girls in whom the Ureters were Transplanted into the Pelvic Colon for Incontinence due to Epispadias without Extroversion of the Bladder. The operation had relieved the incontinence and the kidneys had not been affected by the transplanting of the ureters into the colon.

Mr. STILES further showed two cases of Hydrocephalus in which both common carotids had been ligatured with the object of lessening the secretion of cerebro-spinal fluid, with favourable results.—Dr. SUTHERLAND said that they all appreciated any new method of treatment of this disease. In the congenital cases there was usually a continuous flow of cerebro-spinal fluid and no blocking. It was possible to decide whether blocking of the fluid was present by means of lumbar puncture. Certain cases of syphilitic origin recovered under mercurial treatment. The special type where this operation might do good would be where there was a slight increase of secretion over absorption. Mr. Stiles had spoken very guardedly of results, but with these successes he might certainly be encouraged to continue. Dr. Sutherland referred to his former work on subdural drainage and said that he still believed in it and some patients had certainly been cured by it.—Mr. TUBBY said that these cases were the most successful he had seen.—Dr. SPRIGGS said that Mr. H. S. Pendlebury had suggested draining the ventricles direct into the subcutaneous tissues by carrying silk directly from the ventricles, after the manner of Handley's operation for œdema of the extremities.—Dr. SUTHERLAND said that in drainage methods the great difficulty was in keeping open the passages through the cerebral tissues.—Dr. JOHN THOMSON said that in several cases he had seen a very rapid cessation of increase of the size of the head after this operation. In some cases it had done no good. The head sometimes ceased to increase without operation. He thought the operation a justifiable one.—Mr. R. H. PARRY asked if it had been performed when there was spina bifida present also.—Mr. STILES, in reply, said that his first two cases had been most successful. It was difficult to get suitable cases and the children were often very frail and delicate. He had never seen any benefit when the cases were complicated with spina bifida. Hydrocephalus was more liable to occur after spina bifida was cured when the spina bifida had been excoriated or ulcerated. Congestion might be set up from the region of the spina bifida, which got to the fourth ventricle and set up a true secondary hydrocephalus.

Mr. STILES showed cases illustrating Resection of the Diaphysis of the Long Bones for Diffuse Tuberculous Osteomyelitis. The section was shown the long bones—for instance, the tibia—which had been excised subperiosteally, whilst on the couch lay the patient in whom a new tibia had grown.—Mr. TUBBY congratulated Mr. Stiles on his excellent results in these cases, which he regarded as a most important piece of work.

Dr. CARPENTER expressed a vote of thanks to the Edinburgh gentlemen who had shown cases for giving them a most instructive afternoon. Cases had been shown which it would have been worth while coming three times the distance to see. He hoped that it might lead to further coördination between Edinburgh and London in the study of disease in children.—Mr. LETT, in seconding the vote of thanks, heartily endorsed Dr. Carpenter's remarks.

After tea had been served the section reassembled for the reading of papers.

Mr. TUBBY read a paper on Symmetry and Asymmetry and their Effect in the Production of Lateral Curvature of the Spine.—Mr. PARRY asked if it was Mr. Tubby's experience that the left limb was more constantly longer than the right.—Mr. TUBBY thought not.

Dr. MACALISTER read a paper entitled "Observations concerning the Blood in Chorea and Rheumatism." In experiments made upon the length of life of leucocytes in the blood plasma of patients suffering from chorea and rheumatism he had found that when the corpuscles of a patient suffering from chorea were placed in the plasma of another patient suffering similarly they would live nearly as long as the corpuscles of a healthy person would live in another healthy person's plasma, showing that to some extent the blood cells had become immune to the toxin. This being so, if the toxin in acute rheumatism was similar to that in chorea the same evidence of immunity should exist when the corpuscles of the rheumatic patient were placed in the plasma of a patient suffering from chorea. When this experiment was carried out, however, it was found that the lives of the cells were invariably shortened, and it might be inferred from this that at all events some difference existed between the poisons in the two conditions. Dr. Macalister also supported the observation, previously reported by Cabot, that a marked eosinophilia was present in the subjects of chorea, whereas in acute rheumatism he did not find any increase of eosinophile leucocytes. His observations confirmed the suspicion that there was less real association between chorea and rheumatism than was generally thought to be the case, and therefore that chorea might be due to infective toxæmia of a distinctive character.

Dr. R. G. MCKERRON described a case of Multiple Abscesses of the Liver in a Child, Secondary to Appendicitis.—Mr. LETT referred to the difficulty of diagnosing [illegible] present appendicitis was the most probable cause.

Dr. BURNET read a paper on the Etiology and Treatment of Hyperpyrexia in Childhood. Two cases were described. The first was in a child, aged seven years, with a tuberculous family history. The temperature reached 107° F., and was effectively treated by pouring cold water over the head and neck from a jug. The child was well on the next day and no cause was discovered. The second was that of a boy of eight and a half years s[illegible] was being treated with [illegible] The temperature rose t[illegible] adopted, followed by the application to the head of sponges wrung out of iced water. The patient made an excellent recovery. The hyperpyrexia in this case was ascribed to the development of pericarditis, though Dr. Burnet thought that the salicylates might have something to do with it, especially as the high temperature was accompanied by a maniacal state. He was doubtful as to the safety of applying an ice-bag to the chest in such cases, for this might produce a good deal of shock and perhaps collapse. He recommended tepid sponging in the first instance, followed by the application of cold to the head by sponging or ice-bag. Should these measures fail, the cold douche over the head and neck should be used, the head being held over a basin or bath.—Dr. CARPENTER said that he had used ice-bags in pneumonia and had found that they were borne well except when placed over the heart, when the children collapsed at once.—Dr. SPRIGGS said that he had used ice poultices. They should be made quite thin with gutta-percha tissue because of the pressure. He thought that the harm done by an ice-bag over the heart in children was due to the weight. No weight of any kind should be placed on the front of the chest of a child who was ill, owing to the impairment of respiration which was brought about mechanically.—Dr. MCKERRON had not seen collapse produced by treating pericardial affections with ice.—Dr. SIMPSON said that children who liked it could keep it on very well, but in other cases it caused great discomfort. He emphasised the necessity of keeping the child packed in hot bottles while putting on the ice-bag.

Dr. C. P. LAPAGE described a case of Acute Leucocythæmia in a child, aged eight years, the first symptoms of which were headaches, some wasting, and a slight discharge from the ear, with drowsiness and irritability if roused. After these symptoms had lasted for from seven to 18 days, the child [illegible] tingling and numbness of tl[illegible]re was no history of hæmorrha[illegible]y, fainting, or impairment of vision. On admission, three weeks after the beginning of the illness, the temperature was 100° F., and there were chains of enlarged glands in the axillæ, the groins, the anterior triangles of the neck, the glands being discrete and none of them larger than a pea. There was no œdema, otorrhœa, or exophthalmos. A slight degree of vomiting was present. The stools were loose but showed no other abnormality. The spleen reached down to below the brim of the pelvis, and the liver reached to one inch below the costal margin. There were signs of consolidation at the base of the right lung. The reflexes were increased. Kernig's sign was present, but not well marked. Babinski's sign was present on the right side. The blood count gave red corpuscles 1,600,000, white corpuscles 432,000, hæmoglobin 35 per cent., index 1·1. There was an enormous number of large lymphocytes. The blood was whitish in appearance, resembling blood mixed with pus. It was less coagulable than normal. The spleen diminished in size during the last days of life. Post mortem that organ showed early fibrosis. The bone-marrow of the femur and sternum was red in colour; that of the ribs was apparently normal. Pneumonia was present in the lungs, and there were ecchymoses on the visceral surface of the pericardium, sections of which showed infiltration of lymphocytes. A terminal infection with streptococci and staphylococci was found.

Mr. **Parry** read a paper on the Treatment of Irreducible Intussusception by Lateral Anastomosis. This method of treatment was said in the text-books to be only applicable to chronic cases. Two acute cases were referred to, one Mr. Parry's and one Dr. Rutherford's. On the tenth day in Mr. Parry's case no trace of a tumour could be felt, and this was verified by examination. Mr. Parry put forward, first, the simplicity and safety of the method as compared with excision; secondly, that an alternative line of treatment was afforded to that of severe manipulation in irreducible intussusception; and thirdly, the disappearance of the tumour.—Mr. **Stiles** said that it was a most instructive paper and a landmark in the treatment of irreducible intussusception. He had thought a good deal about the subject and had become almost pessimistic. Patients had died after resection when he thought recovery would take place. He had been agreeably surprised that a good many cases had recovered where there had been extreme difficulty in reducing the intussusception and even after splitting the peritoneal coat. The gangrenous cases were very difficult, and his only criticism of the paper was that the treatment was hardly applicable to these. He said that he had had better results when he operated as quickly as possible, and though the children often looked moribund, it was wonderful, if the treatment was properly carried out—no drugs and plenty of saline by the bowel—how they recovered. Once they had got over the shock he was no longer anxious about them. He thought that this method of Mr. Parry was very sound and he would certainly try it in cases where there was a good deal of difficulty in the attempt to reduce the intussusception.—Mr. **George L. Chiene** said that if the intussusception could not be completely reduced owing to the œdema, a way of getting over the difficulty was by wrapping the portion in three or four large pieces of gauze and compressing it for three or four minutes. It was perfectly easy to do and the child made a good recovery.—Mr. **Parry**, in reply, said that with wider knowledge and means of early diagnosis these difficult cases would not be so often met with and the treatment would resolve itself into reduction in the simple way.

Mr. **Scott Carmichael** read a paper on the Primary Source of Infection of Glands in the Neck. By cutting sections of removed tonsils he had found tuberculous foci in a large proportion of cases.—Mr. **Tubby** had not discovered tuberculosis in the tonsils so often. It would be interesting to know how often the tubercle bacillus was found in adenoids, and in the different tissues of the mouth.—Mr. **Parry** referred to the work on the matter by Dr. Nicoll of Glasgow.—Mr. **Lett** felt convinced that the source of infection was often found in the tonsils, and the operation did not seem complete if the focus was left behind.—Mr. **Stiles** said that in those rapid forms of tuberculosis of the glands in which the whole set of glands was involved in a few weeks it was often found that the tonsils were infected. Even if three-quarters of the tonsil were removed, the healing process destroyed the rest of the disease.

Dr. **Carpenter** moved a vote of thanks to the management of the Royal Edinburgh Hospital for Sick Children for the use of the hospital, and he asked Mr. Stiles to convey their appreciation of the privilege.

Reviews and Notices of Books.

Oliver Wendell Holmes. Centenary Biography. By Lewis W. Townshend. London: Headley Brothers. 1909. Pp. 180. Price 2*s.* 6*d.* net.

Many of us remember the evening at the Royal College of Surgeons of England in 1886 when we were asked to meet Oliver Wendell Holmes. His personality dominated the whole room, and 23 years will not have erased from the memory of those present the intense sense of cultivation, intelligence, and refinement which were the note of the whole man. The centenary of his birth falls this month, and will be celebrated in proper manner in Massachusetts, and in England it is obvious that many remember the anniversary. This volume of Mr. Townshend serves as the *consommé* at the beginning of the anniversary feast.

There have been several lives of Oliver Wendell Holmes written—the full biography of Mr. Morse, jun., that by Miss E. A. Brown (1884), and a monograph by that graceful biographist, Mr. Walter Jerrold (1893), but there are aspects of his work and life still untouched in these volumes which Mr. Townshend has presented, and presented very well. His book is so simple and unpretentious, so careful to give as much Holmes as possible (and as little Townshend), and at the same time so free from adulatory hero worship, that all lovers of the great Boston essayist will turn its pages with pleasure. The early years in the old-fashioned suburb of Cambridge are very pleasantly sketched. But why does Mr. Townshend disguise the name of Dorothy Quincy, the kinswoman of Norman extraction? Why does he not comment on some curious errors of reminiscence and history committed by the poet-professor? Holmes claims to have seen the transit of Venus through a telescope when a child and evolved some striking reflections from the spectacle; there was no transit of Venus between the years 1769 and 1874. He describes Admiral Sir Robert Holmes as having taken part in the "old French war in which Wolfe died." But Sir Robert died in 1692, and the services which he rendered in America were against the Dutch in 1664; we are all very well aware just now that the battle of Quebec was fought in 1759. Oliver Wendell Holmes failed to absorb any of the social life of Paris in 1825, which to writers of another type proved of such intense interest. He made no attempt to enter the society which included Thiers, Hugo, Béranger, George Sand, Balzac, and many other stars. Perhaps it is well that he did not; his own particular individuality as a writer might have been merged and lost. This strong individuality constitutes one of the enduring charms in his style, and probably owes its origin to the latter period of his life at which he laid down the scalpel to take up the pen. The "Autocrat" was not published until he was nearly 50 years of age.

The "Autocrat," the "Professor," and the "Poet" spell Holmes to most of the reading world. Their charm has been so transcendent that it is difficult to realise that the author was ever a working physician and a professor of anatomy (of all subjects), on which he continued to lecture until 1882. But he said "he liked the bones best; they were cleanest." Medicine has now given Holmes his proper due for his published views on puerperal sepsis. He maintained in 1843 that it was the result of direct contagion, "and was confronted by the savage and even abusive opposition of the leading obstetricians in the country." Great credit is due to his direct and logical views when we consider that 30 years later one of the leading obstetric professors in New York pronounced the whole subject in a state of hopeless confusion—a confusion which his own writings did little to improve.

We confess to a poor appetite for Holmes's novels, though no one can fail to see the workings in them of his vigorous imagination and the easy grace of his methods of expression. As a novelist he never found himself. The style is often too digressive and too discursive for continued narration, especially (as Mr. Townshend aptly remarks) when a tragedy has to be developed or heightened. This is particularly marked in "Elsie Venner." With the grounds of attack made by critics when it first appeared we have no sympathy now. The critics were alarmed at the doctrine, then new to many, that inherited predispositions limit the sphere of moral responsibility, "that bad men should be treated as if they were insane." There was a strain of Cotton Mather running through the idea, and Holmes himself recognised this when he wrote to James Freeman Clarke that "theology has been largely diabology." These ideas of responsibility are neither new nor startling to-day, and were not quite new then, for they had their analogue in the philosophy of the good Bishop Myriel presented to the world about the same year by a greater master of fiction from his exile in Guernsey. Those of us who are practising physicians know too well that troublesome class of patients who refuse to grow old gracefully; who expect and endeavour to claim from their ageing hearts and deteriorating vessels and nerve cells the work of early and middle life. An excellent prescription for such persons would be the perusal of the "Tea-cups," our author's last book, his gospel of old age. The polished, genial phrases, the mellow, happy estimate of life, recall the now neglected commonplace books of Southey, the "Omniana" and "The Doctor." Such aftermaths of a literary harvest are rare and deserve study when they present such distinction.

Hypnotism. By Dr. ALBERT MOLL. Translated by A. F. HOPKIRK. London: The Walter Scott Publishing Co. 1909. Pp. 559. Price 6*s.*

HYPNOTISM, both on account of its mysterious nature and because of its frequent exploitation by the charlatan, has in some ways acquired an unsavoury reputation in the world of medical science. Indeed, it is within a comparatively few years that the subject has again been seriously approached with a view to its further elucidation, and it yet remains one which is almost unknown to the large mass of the profession. If hypnotism is used, as it most certainly ought to be, for therapeutic purposes alone, it is of importance that its methods of induction, the cases for which it is suitable, the results which may be expected, and the limitations which surround it should be well known. The book at present under review is one the perusal of which will inform the practitioner upon these various points. It is written with an enthusiasm which impels the author to present the case for the employment of the method with force and skill, but it is also written in a spirit of scientific criticism and with a breadth of view which is worthy of all praise.

After a brief but interesting history of the phases through which hypnotism has passed, the author devotes a large part of his work to the symptoms of the hypnotic state. It is astounding how polymorphic these are, and indeed they appear to be hardly ever identical in two different persons. The chapter on symptoms reads exceedingly like a chapter on the symptoms of hysteria, but Dr. Moll denies that hysterical or nervous patients are particularly susceptible to hypnotism, and he here brings himself into conflict with those who assert that hysteria is a condition of morbid hyper-suggestibility, and that hypnotism by inducing a condition of hyper-suggestibility is in fact inducing hysteria. An interesting chapter on post-hypnotic suggestions reveals the therapeutic possibilities of hypnotism as well as its dangers in unscrupulous hands, and Dr. Moll is most emphatic in his insistence that treatment by this means should be solely in the hands of scientifically trained medical men. The physician alone is in a position to establish a diagnosis, and to thereby determine the indications and contra-indications for treatment in any case. The effect of treatment must be watched and the physician must decide whether or no treatment must be continued. So also it is the physician alone who can determine whether hypnotism is to be supplemented by other methods, and what those methods are to be. For these reasons therefore it is of the highest importance that the therapeutic use of hypnotism by ignorant laymen should be opposed. On the other hand, Dr. Moll is not of opinion that every medical man is fit to undertake the hypnotic treatment of patients, and he considers that the practitioner of hypnotism should have a special faculty both for the induction of hypnosis and for the proper use of the state by practical suggestion. With technical skill and care there is, according to Dr. Moll, no danger of rendering a subject more liable to morbid nervous states, and, moreover, less danger than in many methods of treatment that are termed harmless. It is quite possible that hysteria may occasionally be induced, but such cases are exceedingly infrequent. Even in organic disease hypnotism is not without its uses. The pains of tabes and other organic diseases have been diminished and abolished, while the vomiting of pregnancy and of certain diseases has been alleviated. In many organic diseases the functional disturbance extends much further than the direct influence of the organic lesion would appear to warrant, and it is probable that it is this class of symptom for which hypnotism may be useful.

The book concludes with a chapter on occultism of various manifestations. Occultism has a surprising vogue in these latter days, and it is one of the most astounding features of our educated times that there seems to be an increasing tendency even among the cultured towards the most puerile superstition. Dr. Moll notes how investigators, who in their own lines of work are of world-wide reputation, may be deceived by the clever charlatans who exploit certain so-called occult phenomena. He draws the moral that humility is a supreme virtue in the man of science, while a jargon suggesting familiarity with the unknown and unbending dogmatism are the characteristics of the professors of the occult. In hypnotism, as in other branches of psychology, we have still to recognise that the inner connexion of the body with the mental processes is utterly unknown to us, and that in the exploration of the mystery we must impose severe conditions of criticism and must accept no facts on authority without proof.

As a thorough exposition of a difficult subject we can cordially recommend this work to our readers.

A Manual of Clinical Diagnosis. By JAMES CAMPBELL TODD, Ph.B., M.D., Associate Professor of Pathology, Denver and Gross College of Medicine, University of Denver. Illustrated. London and Philadelphia: W. B. Saunders Company. 1908. Pp. 319. Price 10*s.* net.

THE author states in his preface that the aims of this book are to present a clear and concise statement of the more important laboratory methods which have clinical value, and to act as a brief guide to the interpretation of results. It is designed for the student and practitioner, not for the trained laboratory worker. On the whole Dr. Todd has succeeded in carrying out the above intentions. The methods offered are for the most part practical, but occasionally the tests selected are not the simplest or most convenient for the routine work of the consulting-room.

The chapter on the examination of the sputum contains a good account of the microscopic examination of unstained specimens. Gabbet's method is recommended for the detection of tubercle bacilli, but although the technique may be simple, nevertheless, on account of the difficulty in ascertaining when the decolourisation is complete, we doubt whether it is the most suitable process for practitioners not accustomed to laboratory methods. The chemical examination of the urine is well described, and the qualitative and quantitative tests for the normal and abnormal constituents are accurately given, but the qualitative tests are more complicated than those usually adopted in this country. The microscopic examination of urinary sediments is discussed at length and illustrated by many excellent diagrams.

The chapter dealing with examination of the blood is one of the best in the book; the methods employed in the enumeration of the erythrocytes and leucocytes are clearly explained, and the deductions to be derived from a study of the various forms are fully laid down. Due attention is also given to serum reactions, and the necessary technique is adequately described. The discussion of the opsonic index is, however, scarcely up to date, but if a future edition of the work is demanded this defect can be remedied. The laboratory methods which may be of aid in the diagnosis of disorders of the stomach are also set forth, the chemical tests as well as the microscopic appearances of the discharges being described.

The book is produced in an attractive manner; the type is clear and not trying to the eyes. The illustrations are numerous and form a valuable addition to the letterpress. We do not consider, however, that the work as a whole has any marked superiority to many books on the same subject already existing.

Pye's Surgical Handicraft: a Manual of Surgical Manipulations, Minor Surgery, and Other Matters connected with the Work of House Surgeons and Surgical Dressers. Revised and largely re-written by W. H. CLAYTON-GREENE, B.A., M B., B.C. Cantab., F.R.C.S. Eng., Surgeon in Charge of Out-patients, St. Mary's Hospital; Lecturer on Anatomy in the Medical School. Fifth edition, with 343 Illustrations and Plates newly drawn for this edition. Bristol: John Wright and Sons, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1909. Pp. 592. Price 12*s.* 6*d.* net.

THIS is a practical text-book on the important subject of surgical handicraft—a subject so full of pitfalls to those who have not had the advantage of holding a resident appointment in a general hospital. Mr. Clayton-Greene brings his subjects well up to date, and it may be safely said that the book could only have been compiled by a writer of extensive surgical attainments and teaching ability. The sections dealing with the treatment of fractures, dislocations and sprains, splints, retention and suppression of urine, the use of catheters and other instruments in the bladder, aspiration and tapping of the bladder, hernia, intestinal obstruction, and acute abdominal lesions are particularly well done, and in most of the situations Mr. Clayton-Greene shows clearly the best procedure to be adopted. There are also some interesting sections dealing with special subjects, such as minor surgery of the eye, which is ably described by Mr. Leslie Paton; and diseases of the ear, nose, throat, larynx, and head injuries, each being treated in separate chapters by Mr. H. W. Carson. We also welcome thorough articles dealing with the treatment of the teeth and their extraction, by Mr. Norman G. Bennett; with the treatment of cases of poisoning and urine testing, by Dr. W. H. Willcox; with anæsthesia, by Dr. J. Blumfeld; and with skiagraphy, by Dr. A. Simmons.

The book is well illustrated, and the type is excellent. The index is very satisfactory—always a matter of considerable importance in a work for emergency practice. We only regret that the author has not carried us further into the domains of operative surgery, but the late Mr. Walter Pye originally limited the sphere of the book to work met with in the practice of house surgeons and dressers in surgical wards. We can with confidence recommend this book, and it should find a permanent place in all hospitals—civil and military, naval and colonial—as well as in the library of all practitioners who may wish to keep their "surgical handicraft" in line with modern teaching.

Principles and Methods of Physical Education and Hygiene. By W. P. WELPTON, B.Sc., Master of Method in the University of Leeds. London: W. B. Clive, University Tutorial Press, Limited. 1908. Pp. 401. Price 4*s.* 6*d.*

IN this book the claims of physical training to be regarded as an essential part of the whole scheme of education are fully set forth, and its elevation to something more than a mere practice of muscular movements is discussed. The author claims that the three aspects of education—physical, intellectual, and moral—are intimately related to one another, and insists that they should not be regarded as separate and distinct, but should be coördinated in such a way as to evolve capacity and promote efficiency.

An introductory chapter contributed by Professor Welton of the University of Leeds gives an interesting history of physical education traced from the customs and observances of savage tribes down to the organised physical exercises of the present day, and includes short descriptions of the educational systems in Greek, Roman, and mediæval times written in admirably lucid style. After outlining the scope of his subject, the author devotes several chapters to physiological considerations, with special emphasis on the structure and functions of the nervous system. Fatigue is also considered, and its importance in relation to the organisation of school work, to sleep, and to recreation is discussed. Physical training by means of exercises, games, systems of drill, and gymnastics is dealt with, and useful information is given in a form likely to be of value to those engaged in teaching. Cleanliness, ventilation, and the right attitudes for working and writing are all carefully treated of. A chapter on the care of the eye and another on abnormalities contain directions which should be of service to teachers in regard to the recognition of visual defects and also in detecting cases of illness to which the attention of the school medical officer should be drawn. A table showing the incubation and quarantine periods of the common infectious diseases is also included. The book is carefully written and should be useful, for it abounds in practical suggestions.

LIBRARY TABLE.

Diet in Infancy. By A. DINGWALL FORDYCE, M.D. Edin., F.R.C.P. Edin. London and Edinburgh: William Green and Sons. 1908. Pp. 174. Price 3*s.* 6*d.* net.—This little book contains within its 174 pages a large amount of sound information. The author in his preface says that his book "aims at being of practical utility to practical men working among children," and, in our opinion, his aim will be attained. The book is very simply written, and may shortly be described as a series of canons upon what to do and what not to do. It commences with some general considerations, in which stress is laid by the author upon the fact that the exact composition of mother's milk is unknown, and that although the milk of other mammals can be manipulated so as to approximate superficially to the composition of maternal milk, yet "no manipulation can artificially evolve the inherent peculiarities of that milk." In the section on Substitutes for Mother's Milk, Dr. Fordyce naturally discusses the question of proprietary foods. He is not blind to their occasional usefulness, but he rightly concludes: "When all is said and done, proprietary foods must be considered third-rate food for the infant: in the first class we have mother's milk, and in the second class cow's milk." Parts III. and IV. of the book deal with artificial feeding both in the case of the healthy and the sick infant. It is laid down as an axiom that "cow's milk, boiled (scalded), and suitably modified is the best obtainable artificial food for the infant." In regard to the feeding of sick children, in a passage under the head of improper feeding, Dr. Fordyce makes the following excellent remark: "The most serious element in improper feeding is irregularity. This irregularity is almost never of the nature of too few feeding times; it practically always consists in their over frequency. For infants who are not seriously ill and who are capable of taking a milk mixture of a strength not less than 1 part of milk to 2 parts of water two hours must be the minimum limit between feeding times. It is obviously advisable that the call upon the digestive functions should not be an absolutely continuous one; and more particularly is this the case when an unnatural diet, such as cow's milk, is being administered—and being administered, it may be, of a totally unsuitable composition." This passage is a veritable *memoria technica* for the science and art of the artificial feeding of infants whether healthy or sick. In his consideration of special digestive disorders Dr. Fordyce is eminently sensible. We are glad to see that he insists upon the value of opium for the infant in suitable cases. He recommends the use of it in the form of Dover's powder in doses of from one-sixth to half a grain, "administered under strict superintendence of the varying clinical condition." Finally, he concludes the main portion of his book with a reminder of a matter which is in these days too often forgotten, and that by the rich more often than by the poor—namely, that "mothering" is of great value to the healthy infant and still more so to the sick one. As he well says, "The needs of the infant are not satisfied with occasional feeding and occasional tidying-up." The remainder of the volume is taken up with various appendices mainly of a statistical or analytical nature, although the first and longest of them deals with the question of the complications and disabilities of prolonged lactation and the question of rickets. We are glad to congratulate Dr. Fordyce upon an eminently practical and useful little book.

Practical Guide to the Diseases of the Throat, Nose, and Ear for Senior Students and Junior Practitioners. By WILLIAM LAMB, M.D., C.M. Edin., M.R C.P. Lond., Surgeon to the Birmingham Ear and Throat Hospital. Second edition. London: Baillière, Tindall, and Cox. 1909. Pp. 322 and 55 illustrations. Price 7*s.* 6*d.* net —This edition has been materially enlarged both in scope and in substance. Instead of being confined almost entirely to the examination of patients, as was its predecessor, it now deals more extensively with diagnosis and includes also the treatment of diseases of throat, nose, and ear. Dr. Lamb does not confine himself to mere statements but mostly gives the reasons which he believes to be the correct explanation of the facts, such as why the receding chin, the highly arched palate, protruding teeth, and V-shaped alveolar arch are found in mouth-breathers. These explanations are always plausible and often original. The addition of illustrative cases, though not one we commend in a text-book, are here certainly put to most excellent use and are employed to their best advantage. The chapters on treatment are all of them good and give general or specific directions according to the necessities of the case. Dr. Lamb has added much and well to the scope of his book and for students it will prove a most efficient foundation on which to build up a fuller knowledge.

Transactions of the American Otological Society. Vol. IX., Part 1. New Bedford, Massachusetts: The Mercury Publishing Company. 1908. Pp. 233.—This number, which deals with the events of the forty-first meeting of the society, opens with two obituary notices in memory of Daniel Bennett St. John Roussa and John George Miller The first portion of the meeting was devoted to the exhibition of new instruments and card specimens, after which a discussion on otosclerosis, covering practically the whole range of the present knowledge of the disease, was opened by Dr. T. J. Harris with regard to etiology, by Dr. W. Soher Bryant with regard to pathology and prognosis, and by Dr. G. E. Shambaugh with regard to symptoms and diagnosis. Then follows a paper by Dr. B. H. Potts on Non-purulent Labyrinthitis as a Complication of Acute Middle-Ear Suppuration, based on three cases of this rather unusual condition. Dr. B. A. Randall reported a case of fatal sepsis after fracture of the temporal and occipital bones; Dr. E. Gruening a case of thrombosis of the left lateral sinus followed by thrombosis of both the cavernous and other sinuses of the dura mater; Dr. E. B. Dench a case of acute suppurative labyrinthitis; and Dr. Leland a case of double otitis media, complicated by extradural and intradural abscess. Dr. Charles J. Clipp reported a case in which double optic neuritis and paralysis of the left external recti occurred. Dr. Crockett reported a case of vertigo, in which relief but not complete recovery was obtained by removal of the stapes. A brief historical and critical review of operations for the cure of chronic middle ear suppuration was contributed by Dr. Noble H. Pierce, and Dr. C. H. Snow made further observations about the necessity for operation. Dr. Percy Friedenburg read a paper in which he described a few of the acoustic functions of the labyrinth, and concluded with an extremely able and critical review of our present knowledge of static and dynamic equilibrium. Dr. Shambaugh read a paper on epithelioma of the sulcus externus.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In the July issue Dr. Byrom Bramwell records the post-mortem findings in a case of pseudo-hypertrophic paralysis; the spinal cord showed curious fissures and disturbances of the normal arrangement of grey and white matter. These appearances are regarded by van Gieson as artefacts due to post-mortem changes, but it is remarkable that they were present in three cases out of four of this disease observed by Dr. Bramwell, and only in four others of all the necropsies made by him. Dr. Angus MacGillivray writes on the diagnosis and treatment of pneumococcal and diplobacillary hypopyon keratitis; and Mr. Alexander Don on cancer of the penis: Dr Alexander Goodall records his experience in investigating the physiological action of extract of ergot, which appears to have a distinct action on the uterus apart from that exercised on the blood-vessels, and Dr George A. Pirie describes a year's work with X rays in diagnosis at the Dundee Royal Infirmary.

The Dublin Journal of Medical Science.—In the July number Mr. Leveson Gower Gunn narrates a series of cases of post-operative tetanus which occurred in spite of antiseptic precautions. The exact source of infection was not discoverable, but lay probably in the cat-gut employed. It was not possible to isolate the bacilli from the cadavers. Dr. Richard L. Sutton of Kansas city, U.S A., describes the use of "snow" of carbon dioxide as a cautery in cases of cutaneous disease, especially in nævi and lupus erythematosus, and gives a bibliography of papers dealing with this mode of treatment; and Mr. E. Hastings Tweedy contributes a first instalment of his report of the *Rotunda Hospital.*

The Birmingham Medical Review.—A lecture by Dr. David Fraser Harris on the history of the discovery of the circulation of the blood—the first of a course on the Essentials of Physiological History—gives an interesting account of the development of knowledge on this subject from Hippocrates to Harvey. Mr. Smallwood Savage writes on tuberculous salpingitis, and narrates two cases of the affection, in one of which the infection seemed to have arisen from the intestine and in the other to have been conveyed from some distant focus by the blood-stream.

The Medical Chronicle.—A valuable paper on physiological variations in children by Dr. James Kerr appears in the July issue of this journal. He points out the correlation often present between physical and mental defect in children attending public elementary schools, and calls attention to such conditions as word-deafness, and word-blindness which cause an appearance of intellectual deficiency. He regrets the report made by the Commission on the Care of the Feeble-minded, which tends to lump all mental defects together and to discourage due classification for purposes of treatment. Dr. R. T. Williamson discusses the geographical distribution of diabetes mellitus and brings out some curious facts. The death-rate from this malady is rising in England and in most highly civilised countries, but the cause of this incidence is not entirely clear. An annotation on this paper will be found in our issue of July 24th (p. 244).

The Liverpool Medico-Chirurgical Journal.—The current (July) number of this periodical contains, as usual, many interesting papers. We can only mention a few. The value of tuberculin as a remedy is discussed in two articles, one by Dr. George A. Crace-Calvert and the other by Dr. Henry Clarke and Mr. Charles E. P. Forsyth. In both favourable opinions are expressed, and the oral mode of administration is considered to be efficacious. Dr. N. Percy Marsh and Dr. Owen T. Williams write on the treatment of cerebro-spinal meningitis and advise the use of Flexner and Jobling's serum and of lumbar puncture. Dr. John Hay records two cases of recurrent hæmoptysis in non-tuberculous patients, one being a case of angioneurotic œdema and the other of a pulmonary abscess cavity; and Dr. Frederick P. Wilson discusses the sero-diagnosis of syphilis, which he considers a valuable means of recognising the disease.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on July 29th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The following candidates having passed the required examinations were admitted Members of the College:—Edwin Greaves Fearnsides, M.A., M.B. Cantab., L.R.C.P.; W. Errington Hume, M.B. Cantab.; James Lindsay, M.D. Edin.; Henry MacCormac, M.B. Edin.; Walter Malden, M.A., M.D. Cantab.; Arthur Hallowes Miller, M.B. Cantab., L.R.C.P.; Patrick Thomas O'Sullivan, M.D. Royal Univ. Irel.; Leonard Gregory Parsons, M.D. Lond., L.R.C.P.; and Ivy Evelyn Woodward, M.D. Lond.

Eighty-six candidates having passed the necessary examinations were granted Licences to practise physic, and 17 candidates were recommended by the examiners for the Diploma in Public Health.

The PRESIDENT announced that he had received a communication from the Secretary of State for Home Affairs requesting him to nominate a delegate to represent this country at the International Medical Congress to be held at Budapest this year. The President nominated Dr. F. W. Pavy, who had already been requested to represent the College on this occasion.

The following communications were received:—1. From the secretary of the Royal College of Surgeons of England reporting proceedings of their Council on July 8th. 2. From the University of Edinburgh in reference to the examination for the Murchison memorial scholarship, stating that as a result of the recent examination the scholarship had been awarded to Mr. Alexander Gibson, M.A., M.B., *proxime accessit* Mr. J. G. Greenfield, M.B., Ch.B.

The following list of Censors, other College officers, and examiners was adopted by the College:—Censors: Sir William Henry Allchin, Dr. Francis de Havilland Hall, Dr. Seymour John Sharkey, and Dr. James Kingston Fowler. Treasurer: Sir Dyce Duckworth. Registrar: Dr. Joseph Arderne Ormerod. Harveian librarian: Dr. Joseph Frank Payne. Elected members of the library committee: Dr. Norman Moore, Dr. William Osler, Dr. Arthur Francis Voelcker, and Dr. Charles Arthur Mercier. Curators of the museum: Sir William Henry Allchin, Dr. Seymour John Sharkey, Dr. William Hunter, and Dr. Frederick William Andrewes. Finance committee: Dr. Francis Henry Champneys, Dr. George Newton Pitt, and Dr. Herbert Pennell Hawkins. Examiners: Chemistry—Mr. W. Holdsworth Hurtley and Mr. George Senter. Physics—Dr. Dawson F. D. Turner and Mr. Alfred Henry Fison. Practical pharmacy—Dr. Arthur Philip Beddard, Dr. Robert Arthur Young, Dr. Edmund Ivens Spriggs, Dr. William James Fenton, and Dr. Alfred Ernest Russell. Physiology—Dr. William Dobinson Halliburton and Dr. Marcus Seymour Pembrey. Anatomy—Dr. Christopher Addison. Medical anatomy and principles and practice of medicine—Dr. Wilmot Parker Herringham, Dr. Richard Grainger Hebb, Dr. Sidney Harris Cox Martin, Dr. Herbert Pennell Hawkins, Dr. Humphry Davy Rolleston, Sir Edwin Cooper Perry, Sir Hugh Reeve Beevor, Dr. James Galloway, Dr. Wilfred James Hadley, and Dr. Laurence Humphry. Midwifery and diseases peculiar to women—Dr. Herbert Ritchie Spencer, Dr. Arthur Hamilton Nicholson Lewers, Dr. George H. Drummond Robinson, Dr. Arthur Francis Stabb, and Dr. George H. A. Comyns Berkeley. Public health—Part I., Dr. William Henry Willcox; Part II., Mr. Alexander Grant Russell Foulerton. Murchison scholarship—Dr. David Bridge Lees and Dr. Horace George Turney.

The following awards were recommended by the Council: 1. The Baly medal, for distinction in the science of physiology, to Emil Fischer, Ph.D., Professor of Chemistry, University of Berlin. 2. The Moxon medal, for distinction by observation and research in clinical medicine, to Sir William R. Gowers, M.D., F.R.S.

A report was received from Dr. Norman Moore on the Darwin commemoration at Cambridge, June 21st to 25th.

A report was received from Dr. J. H. Habershon on the celebration of the 350th anniversary of the foundation of the University of Geneva, July 7th to 10th.

A report was received and adopted from the Standing Committee on Beri-beri after a meeting held on May 19th last.

The annual report of the Imperial Cancer Research Fund was received and adopted. Dr. Sidney H. C. Martin was re-elected a member of the executive committee of the above fund.

A report, dated June 29th, from the Committee of Management was received and adopted. The report recommended:—

1. That the London County Council Asylum at Long Grove, Epsom, be added to the list of lunatic asylums recognised by the Examining Board in England.

2. That the Western Reserve University, Cleveland, Ohio, United States, be added to the list of institutions at which the curriculum of professional study required for the diplomas of the Royal Colleges may be pursued, and whose graduates may be admitted to the Final Examination of the Examining Board in England on production of the required certificates of study.

A second report from the same committee, dated July 13th, was received and adopted. The committee recommended that Mr. R. J. Godlee be appointed visitor to the examinations of the Egyptian School of Medicine for the examinations to be held in December next.

The Registrar (Dr. J. A. Ormerod) was elected a member of the committee of management in place of Dr. E. Liveing, who has resigned.

On the motion of the SENIOR CENSOR (Dr. NORMAN MOORE), seconded by Dr. P. W. LATHAM, Dr. E. Liveing was elected by acclamation Emeritus Registrar.

Dr. LIVEING expressed his thanks to the College.

The annual report of the Library Committee, the quarterly report of the College Finance Committee, and the annual report of the Curators of the Museum were received and adopted.

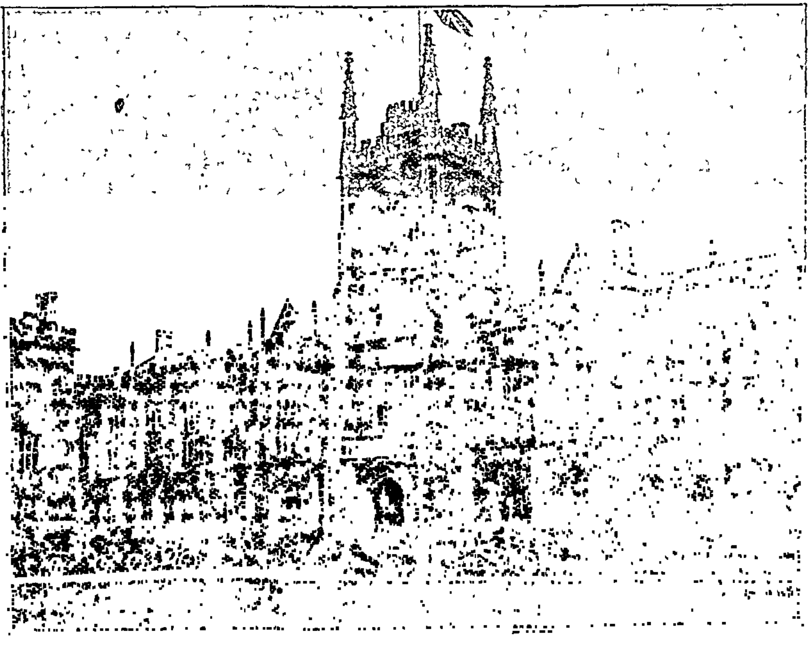
The books and other publications presented to the library during the past quarter were received and the thanks of the College returned to the donors.

After some further formal business the PRESIDENT dissolved the Comitia.

THE BRITISH MEDICAL ASSOCIATION.

SEVENTY-SEVENTH ANNUAL MEETING AT BELFAST.

IN reviewing the recent meeting of the British Medical Association at Belfast it will, we think, be conceded that the scientific fruits were well up to their usual standard, and there is little doubt that those aspects of medicine in which the intelligent coöperation of the public is desirable, notably the progress of public health, attracted an unusual amount of popular attention in the district in which the Congress was held. This was due in no small degree to the energetic attendance of the Earl and Countess of Aberdeen at so many of the gatherings of the week, for they not only honoured with their presence the four addresses delivered in plenary congress but assisted at several of the sectional meetings, notably at those in which some problem connected with tuberculosis came up for discussion. Indeed, Lady Aberdeen's zeal for the anti-tuberculosis crusade did not confine itself to the walls of Queen's University, but between the acts of an interesting performance of folk plays given in the opera-house by the Irish Literary Society to the ladies of the Congress and their friends whilst the annual dinner was in progress elsewhere, the founder and President of the Women's National Health Association of Ireland gave a lecture on the origin and progress of that admirable movement, illustrated by lantern slides showing the work that is being done by its travelling museum, caravans, lecturers, and pamphlets.



Queen's University, Belfast, in which the meetings of the British Medical Association were held.

The excellent and spirited Address in Obstetrics by Sir John Byers, which we print on another page, was delivered in the University library at the last of the scientific gatherings attended by the Lord Lieutenant and Lady Aberdeen. At its close, Sir William Whitla, the President, moved a vote *of warm thanks for the distinction which their Excellencies'* presence had given to the whole of the meeting, a motion which was carried by acclamation, and in replying His Excellency paid a high compliment to Sir John Byers's discourse, as having been "instinct not only with scientific knowledge and research, but also with hopefulness for the future." Subsequently Sir John Byers and Lady Byers entertained at luncheon the same two distinguished honorary members of the British Medical Association with some 40 other guests, who included the Lord Mayor and Lady Mayoress of Belfast, Sir Lauder Brunton, Sir Malcolm Morris, Sir Almroth Wright, Sir William J. Thompson, Sir James Barr, Professor E. Fuchs (Vienna), Professor A. J. Smith, the Master of the Rotunda, Dr. T. N. Kelynack, Professor H. Corby, Professor Cullen (Baltimore), Mr. P. J. Freyer, Mr. J. S. Bryars, Dr. H. Chambers, Dr. C. Magill, Mr. Guy Elliston, the Editor of the *British Medical Journal*, and the representative of THE LANCET.

The annual summer meeting and luncheon of the Irish Medical Schools and Graduates' Association was held at the Medical Institute, Belfast, on July 28th. There was a large attendance of members and guests, including ladies. Sir Charles Cameron (Dublin) was in the chair, and amongst those present were the Rev. Dr. T. Hamilton (Vice-Chancellor, Queen's University, Belfast), Mr. Sinclair White (retiring President of the British Medical Association), Dr. E Rayner (honorary treasurer), Dr. Dawson Williams, Dr. J. A. Macdonald, Mr. H. A. Ballance, Mr. R. H. Kinsey, Mr. J. Smith Whitaker, Dr. A. Cox, Mr. Guy Elliston Mr. Shepherd

Boyd, Dr. R C. Buist, Dr. P. Vernon Dodd, Dr. R. Fegan, Dr. J. H. Ewart, Dr. S. Agnew, Rev. Dr. R Seaver, Dr. J. J. Macan (chairman of Council), and Mr. T. Hobbs Crampton and Dr. W. Douglas (honorary secretaries).

The annual dinner of the British Medical Association was held in the Ulster Hall on Wednesday, July 28th, the President of the Association in the chair. A distinguished company attended the dinner, including the leading members of the Association, a representative gathering of local medical men, and many prominent Belfast citizens. After the toast of "The King" had been duly honoured the President rose and, turning to the Earl of Aberdeen who sat on his right hand side, proposed the toast of "The Lord Lieutenant and Prosperity to Ireland." After referring to the labours of the Lord Lieutenant in the domain of preventive medicine in Ireland the President announced that the Council of the Association had decided to elect the Countess of Aberdeen as an honorary member of their Association in recognition of her successful efforts in the prevention of tuberculosis. The Lord Lieutenant, in reply, thanked the Association for the distinction conferred on the Countess, and referred to the report of the Registrar-General of Ireland, which acknowledged the campaign against tuberculosis carried on through the agency of the Women's National Health Association of Ireland. The next toast was that of "The British Medical Association," which was eloquently proposed by the Bishop of Down and Connor and Dromore. He sketched the rise of the Association and eulogised the labours of its members. He particularly praised the hopefulness of medical men and described their cheerful optimism as one of the splendid things which gilded life with hope. This toast was acknowledged by Dr. J. A. Macdonald, the chairman of the representative meeting, who in the name of the Association thanked the people of Belfast for the generous welcome its members had received. The next event of the evening was not on the official programme, but it certainly elicited the most hearty acknowledgment, everyone cheering and acclaiming Dr. T. S. Kirk as he formally presented a silver cup, the gift of the Ulster Medical Society, for a golfing competition for members of the Association to be held annually. The cup, which is an accurate copy of the famous Ardagh Chalice, a beautiful and famous piece of old Irish silver, was accepted by the President in a graceful speech of thanks to Dr. Kirk, the President of the Ulster Medical Society. The next toast was that of "Our Guests," and this was entrusted to Sir Peter R O'Connell, who extended a hearty welcome to the numerous guests present. This toast was acknowledged by the Lord Mayor of Belfast, by Professor J Fehling of Strasburg, and by Dr. D. B. Delavan of New York. Sir T. Clifford Allbutt then proposed the health of the President, and after the President had made a suitable reply the health of Dr. Cecil E. Shaw, one of the honorary secretaries, was enthusiastically drunk and briefly acknowledged by that gentleman.

The Temperance Breakfast, which is now a regular feature of the Association's meeting, was held this year in the central hall of the Municipal Technical Association under the joint auspices of the National and Irish Temperance Leagues. The Lord Mayor of Belfast as the chairman of the latter body was the fitting president at the breakfast on July 29th, a gathering which attracted a surprising number of people, seeing that it was held at 8 o'clock in the morning. The chairman was supported by Sir James Anderson, Professor Crothers (Hartford, Connecticut) Dr. T. N. Kelynack, Mr. W. McAdam Eccles, Dr. Norman Porritt, and Mr. J. T. Rae. After the Lord Mayor's address on the progress of the temperance movement in Ireland—"he remembered the time in Belfast when it was hardly respectable to be a teetotaller"—Dr. Kelynack gave an interesting *résumé* of the principal facts relating to the scientific study of alcoholism as revealed at the recent London congress on the subject. He showed that systematic research into the question has only just been entered upon, and that paths of inquiry are opening out in many directions, but that the great attention directed to the movement by such public gatherings under scientific auspices as he was then addressing would result in a "real advancement in our perception of the causes and conditions of alcoholism, which shall finally enable us to arrest a malady threatening the very existence of the nation." Dr. Kelynack's able and temperate address was listened to with much interest by the large company.

The annual luncheon of the Continental Anglo-American Medical Society was held at the Grand Central Hotel, Belfast, on July 29th, Professor W. Osler occupying the chair. Over 40 members and guests were present. These included Professor Bryson Delavan and Dr. Emil Mayer (New York), Professor Fehling (Strasburg), Professor Calmette (Lille), Professor Jacobs, Dr. Bordet, Dr. Delsaux, and Dr. Toubeau (Brussels), Dr. L. Wickham (Paris), Sir Lauder Brunton, Bart., Sir Malcolm Morris, Sir James Barr, Mr. George Chiene, Mr. E. Treacher Collins, Mr. P. J. Freyer, Mr. Richard Lake, Dr. Arnold Lawson, Dr. Louis C. Parkes, Dr. Edwin Rayner, Mr. E. Hastings Tweedy, and Dr. Dawson Williams. The society was represented by Professor Osler and Professor StClair Thomson (Honorary Presidents), and by Dr. G. S. Brock (Rome), Dr. A. R. Coldstream (Florence), Dr. L. N. Robinson (Paris), Dr. D. W. Samways (Mentone), Mr. P. J. Thomson (Brussels), and Dr. C. G. Jarvis (Paris), honorary secretary. Professor Osler proposed the toast of "Prosperity to the Society," referring in humorous terms to the plight of the British or American traveller in the hands of a foreign medical man unable to understand the English language. He pointed out the value of the society not only in uniting the British and American practitioners in Europe and Northern Africa, but also in bringing to the notice of physicians at home the names of trustworthy doctors of their own nationality to whom they could entrust their patients travelling abroad Dr. Brock replied for the society and proposed the health of the guests, coupled with the names of Professor Calmette and Professor Delavan and Dr. J. Walton Browne, who made suitable replies. This very successful meeting was brought to a conclusion by the toast to the chairman, proposed by Dr. Samways and received with acclamation.

But if the presence of the King's representative lent an exceptional interest to some of the scientific work of the Congress, it goes without saying that its social side gained a great deal from the same cause. Perhaps its climax was reached in the City Hall on Thursday, July 29th, when the Lord Mayor, Sir Robert Anderson, and the Lady Mayoress gave a civic reception to the members of the Congress, which the Viceregal party attended officially. The scene in the great hall was brilliant in every sense of the word, for academic costume was in evidence to a greater extent than is usual, and included gowns and hoods of a symbolical colour range defying the interpretation of any but a professed robe-maker. The fine suite of reception-rooms and corridors extending round the four sides of the beautiful building, together with the upper and lower vestibules, were all well peopled before the close of the entertainment by a company which must have numbered nearly 2000 and which did not disperse till after midnight, when its more energetic members were winding up the evening with an impromptu dance in the great hall.

Another pleasant entertainment was given on the following evening by the President and members of the Ulster Branch of the Association in the Botanic Gardens belonging to the city and adjoining the University. An array of marquees had been provided against the weather, but the rain mercifully held off until the party was breaking up, when it made up for its abstinence with a relentless downpour. The gardens had been illuminated with excellent effect, and the tropical palmarium, which contains some perfectly grown tree-ferns, banana trees, and palm trees, and a fine specimen of the Victoria Regia lily, attracted many visitors to promenade its galleries or linger in its grottoes. Good entertainment, too, was provided in special pavilions, and in the opinion of many this function, which brought the meeting to its official close, was the most attractive of the week's festivities.

Much other private hospitality was enjoyed by members and visitors during the week. Sir William and Lady Whitla gave a garden party in their beautiful grounds, and Mr. and Mrs. M'Mordie a like entertainment The Royal North of Ireland Yacht Club not only entertained a party at Cultra, but furnished such of them as wished to try their seamanship with boats of the No. 2 class for a race, in which Dr. J. T. Wigham (Dublin) won the first prize and Dr. W. H. Brailey (Hove) the second. Mr. James Davidson, chairman of the Royal Victoria Hospital, held a crowded reception at that model institution on the Thursday afternoon, and earlier in the week the medical staff of the Mater Infirmorum Hospital welcomed the Association in a similar manner. At the Victoria Hospital a large number of interested visitors were admitted "behind the scenes" of the Plenum system of ventilation, and were blown down the huge ventilating shaft in the stiff breeze sent along it by the electric fans. The model laundry also came in for a good share of attention.

The great industrial houses of the city were not behindhand in hospitality, and many of them threw their works open to the inspection of visitors. Perhaps the vast shipbuilding yards of Messrs. Harland and Wolff attracted the largest crowd, which was permitted to wander where it would and gain a first-hand appreciation of the amount of patient labour that is driven with the rivets into a modern steel-built vessel. Messrs. Workman and Clark also entertained a party at their works. Messrs Dunville and Co gave a luncheon at their warehouse, afterwards showing their guests over their famous whisky distillery, whilst Messrs. Gallaher's tobacco factory, the large Belfast ropeworks, and the York Street Flax Spinning and Weaving Company all offered to interested visitors opportunity to watch the various phases of their respective industries in full working activity. Not the least attractive part of these annual congresses is the welcome which such prominent manufacturing firms are accustomed to offer to their city's medical visitors, who seldom elsewhere get the chance of taking such impressive object-lessons in the progress of modern industrial enterprise. And lastly, the various railway companies serving Belfast gave the Association special facilities for reaching the Giant's Causeway, the Mourne Mountains, and the Antrim coast on the Saturday following the close of the Congress, a day blessed with unexpected sunshine. The party that chose the Mourne district was entertained by the hospitable Warrenpoint urban council, which showed them the beauties of Carlingford Lough and of Rostrevor.

The golf-match on the links of the Royal County Down Golf Club at Newcastle for the handsome Belfast cup presented to the Association by the Ulster Medical Society for [illegible] the members of the British Medical [illegible] on July 30th, and attracted over 200 [illegible] The arrangements for this popular event were in the hands of Dr. T. S. Kirk, on whose organising powers the smoothness with which the competition was carried through reflects the greatest credit. Several special trains left Belfast for Newcastle and all the players and their friends were entertained to luncheon in the club house by *Dr. and Mrs. Kirk. The links were in excellent order* and the officials of the Royal County Down Golf Club were untiring in their efforts to secure the comfort of their many visitors. General admiration was expressed at the beautiful and sporting course which lies at the foot of Slieve Donard, the highest peak of the Mourne Mountains which sweep down to the sea in easy, graceful lines. The competition was favoured with brilliant sunshine. The smooth lawns round the club house were occupied by a bright group of ladies engaged in a putting competition and close by Mr. R L. Bell and Mrs. Bell, with the assistance of many lady friends, dispensed tea to the company. Towards the end of the afternoon the winner of the Belfast Cup was proclaimed by Dr. Kirk to be Dr. R. A. Shackleton of Holywood and this gentleman received the cup from the hands of Mrs. Kirk. Dr. Shackleton's score was 2 up on bogey with a handicap of 14 A second prize was gained by Mr. G. L. Chiene of Edinburgh, who was 3 down to bogey. Before the company left for Belfast Dr. Shackleton, in a neat speech, voiced the thanks of all present for the splendid hospitality accorded to the visitors, and the enthusiastic rendering of "For They are Jolly Good *Fellows" was at least remarkable for its volume.*

In conjunction with the annual meeting of the Medical Library Association an exhibition of over 200 valuable and interesting medical MSS., books, photographs of libraries, &c., was held in the engineering drawing room, Queen's University, Belfast, from July 27th to 30th, under the curatorship of Dr I. W. Hall and Mr C. E. A Clayton, honorary secretaries of the association The exhibition was divided into seven sections Two MSS in Section 1 call for special attention, one English, of the fourteenth century, on Urine (Manchester Medical Society), and another on the same subject, about the same date, in Latin and Irish (Trinity College, Dublin). Section 2 contained 15 volumes printed before 1500, amongst them the first edition of "Celsi de Medicina Liber," 1478 (Dr. Lloyd Roberts); the works of Mesue, 1478 (Bristol Corporation); the Surgery of Guy de Chauliac, 1480 (Manchester Medical Society); and the "Anathomia" of Mundinus, 1493 (Dr. Lloyd Roberts). Amongst the books printed since 1500, Section 3, were two copies of Raynalde's "Birth of Mankind," 1528 and 1613 (Dr. Lloyd Roberts and the Bristol Medical Library); Faer's "Regiment of Lyfe," 1567, and Paynel's "Regimen Sanitatis Salerni," 1541 (both by Dr Lloyd Roberts); and a pamphlet on "Variolous Contagion," 1808, by Jenner (Professor J. A. Lindsay). An exceptionally fine collection of books by Irish authors or printed in Ireland formed Section 4, lent principally by Dr. T. P. C. Kirkpatrick of Dublin, and the Royal College of Physicians of Ireland. Professor W. Osler had lent two interesting collections of books relating to Michael Servetus, whose quatercentenary occurs this year, and Ulrich von Hutten, the scholar-knight who described the treatment of syphilis in his own person. The final section contained a series of books on consumption, commencing with Celsus, who recommended an open-air treatment and milk diet, and ending with the Countess of Aberdeen's "Ireland's Crusade against Tuberculosis." Valuable books were also lent by the Royal College of Surgeons of England, Stevens' Hospital, Dublin, Sir W. Whitla, Dr. W. L. Storey, Mr. R. M. Young, Ulster Medical Society, Dr. Marion B. Andrews, Mr. E. G. Clayton, Queen's University, Belfast, Linen Hall Library, Belfast Corporation, Dr. G. Parker (Bristol), Bristol Medical Library, Mr. Swanston (Belfast), and Mr. Sommerville (Sheffield). Messrs. Bell and Mayor had also most generously loaned a number of covered cases.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 28TH.

President, Professor JAMES ALEXANDER LINDSAY (Belfast).

In continuing the discussion on

Angina Pectoris,

of which we reported Sir T. CLIFFORD ALLBUTT'S opening remarks in our last issue,

Sir T. LAUDER BRUNTON (London) agreed that the aorta might be one of the sources of anginal pain, but did not think it was the only one. He also opposed the suggestion of Sir Clifford Allbutt to abolish the term pseudo-angina. it was convenient to differentiate two distinct classes—pseudo-angina, occurring in younger people and not relieved by vaso-dilator drugs; and true angina, of more serious nature, in older people, and relieved by vaso-dilator agencies. One of the great difficulties was our imperfect knowledge of the sensory or afferent nerves of the heart, and he pointed out the difficulties in the way of their experimental investigation. He said there were very few researches on the function of the cardiac plexus, and yet Sir Clifford Allbutt asserted that it was motor in function. Sir Lauder Brunton regarded the pain in angina pectoris as similar to that in the bladder when it was distended and had to contract against resistance. He also stated that stretching of the serous covering of the bladder or intestine did not give rise to pain. It was only when the muscular fibres began to contract that the pain was felt. He referred to some experiments of Professor Kronecker showing that some muscle fibres of the heart might pass into a condition of cramp. In regard to the pain of angina pectoris this might occur at the apex of the heart as well as at the manubrium sterni. He agreed that cases might recover or remain well for years, but thought there was a greater tendency to sudden death afterwards. He also discussed the treatment and referred to his own observations made in 1867 on the value of vaso-dilator drugs.

Professor W. OSLER (Oxford) referred to the greater frequency of angina pectoris in the United States of America. He separated three groups of cases, the first corresponding to that described by Sir Clifford Allbutt and associated with local aortitis or peri-aortitis, a second group with disease of the coronary artery, and a third and more exceptional class with neither disease of the coronary artery nor of the aorta. He therefore was of opinion that Sir Clifford Allbutt's view did not hold in all cases. He confessed his own affection for the old theory of Allan Burns of intermittent claudication, while admitting that it also did not hold in all cases.

Dr. W. K. HUNTER (Glasgow) recorded some observations on a case of angina pectoris with a record of the pulse and blood pressure. He was of opinion that the most successful treatment in these cases was to lower blood pressure.

Dr. W. GORDON (Exeter) brought forward two observations, first, that he had often found the pulse tension higher in the recumbent than in the erect or sitting posture, and he offered this as a suggestion to explain the attacks which occurred during sleep. The second point was that the evidence of cardiac dilatation was often more easily obtained in the erect than in the recumbent posture.

Dr. JOHN HADDON (Denholm, Hawick) referred to the effects and importance of diet in this condition.

Sir CLIFFORD ALLBUTT then briefly replied.

Dr. D. W. SAMWAYS (Mentone) read a paper on

Misconceptions Concerning the Riviera.

He deprecated the tendency among some members of the medical profession to follow fashion in recommending continental health resorts and complained that the Riviera, like many others, had been petted and dropped. He then discussed *seriatim* certain misconceptions in regard to the Riviera, the first being that it was usually supposed to possess a marine climate, but he insisted that the mountains behind it dominate the character of its climate, and claimed that statistics showed that its climate was that of the mountains. The air set from these mountains at night time towards the sea and the air in the day was simply a return of the mountain air landwards. The second misconception to which he referred was the supposed treacherous character as regards climate owing to the fact that some healthy persons contracted severe colds during their stay there. This was, he maintained, due to their neglect to adapt their clothing and their habits to the nature of the climate. The charge of inconstancy he denied entirely, stating that it was almost too constant for some invalids, for whom a change of climatic conditions was often advantageous. The third misconception was the supposition that invalids, and especially tuberculous patients, were unwelcome, and the fourth, that the so-called English Riviera afforded better conditions than the French, which he emphatically denied.

Dr. W. GORDON (Exeter) read a paper on

The Influence of Soil on Phthisis.

He urged the necessity in dealing with such problems of securing the approximate isolation of influences and proceeded to give a brief historical *résumé* of our knowledge of this subject, referring especially to the statement of Sir George Buchanan, affirming a definite relation between the death-rate from pulmonary tuberculosis and the dampness of the subsoil. He also mentioned his own observations on the effect of strong prevalent rainy winds in this connexion and was of opinion that this was a more important factor. He gave details of some statistics he had collected in regard to this matter from Exeter and its surrounding district and stated that the statements of Buchanan were neither proved nor disproved. He also gave tables showing the phthisis death-rates in the sheltered streets of Exeter and in some sheltered parishes classified according to the geological nature of the subsoil, and stated that it was difficult to get away from the conclusion that soil did influence the death-rate.

THURSDAY, JULY 29TH.

Dr. W. TYRRELL BROOKS (Oxford) opened a discussion on

The Medical Aspects of Athleticism.

He pointed out that boys found pleasure in the comparative detachment from work which games afforded at school. He also referred to their value educationally in developing the power of organisation, which was a great force in developing character. There had been a revulsion of feeling in recent times against relying upon the results of examination alone as a test of capacity, as instanced in the conditions of the Cecil Rhodes scholarships. He believed that athletics or physical training in some form were necessary in schools. He drew a contrast between the preparatory school boy at 14 and the robust type of undergraduate at 18 or 19 years of age, and believed that the most robust type of undergraduate came from those schools with the most strenuous athletic exercises. He had endeavoured to collect statistics of the mortality among school boys due to athletics during the past 20 years, and had addressed inquiries to a number of schools. He had received 13 replies, embracing records of 6500 boys, among whom there were five deaths, of which three were purely accidental. One was a boy killed from damage to the lesser bowel sustained through a charge in Rugby football, while two occurred in gymnasiums, one boy being choked by regurgitation of food from the stomach, another case died a year after fracture of the cervical vertebræ sustained through a fall. Two other cases occurred which would be dealt with by Dr. Clement Dukes. During the same period two deaths occurred at the University of Oxford, one during a game of hockey; the man, who was the subject of double aortic disease, had been warned of his danger in so doing; the other was a high jumper, who, after a heavy indigestible meal, ran a few paces preparatory to a jump and fell dead. Dr. Brooks had also collected the cases of sudden death occurring among apparently healthy boys apart from athletics during the same period and found four cases, one being a case of sudden heart failure due to going into the water, the stomach being full of cherries at the time. Three other cases were probably due to cerebral causes. He wished to insist on the importance of securing a post-mortem examination in all cases of sudden death during games. Passing on to conside the organs likely to be damaged by athletics, he first discussed the heart and maintained that it was difficult to establish the effects upon this organ The observations of Dr W Leslie Mackenzie upon the hearts of children had shown that the heart area might often appear abnormally large and that the rhythm was less constantly regular than in adults, facts which minimise the value of these signs It was also of importance to investigate the possibilities in older persons of excessive smoking, gluttony insufficient rest, and sexual excesses, and also to remember the effects of toxins produced during febrile attacks leading to damage during and after convalescence He agreed with the view of Sir Clifford Allbutt that the young and healthy heart was so resilient that it was impossible for any damage to be done to it by ordinary muscular exercise In regard to the lungs he advised that boys with asthma should be restrained from strenuous exercise He strongly supported the recommendations of the Association of Medical Officers of Schools that every boy on entering a school should undergo a thorough medical examination, that his fitness for physical exercise should be determined by his physique and constitutional ability and not by his age, that there should be careful observation of the younger boys during their games, that an ample interval should be allowed between the previous meal and the beginning of exercise, and that special caution should be exercised in permitting resumption of games after convalescence from illness Referring then to the two forms of exercise which had been subjected to the most severe criticism—viz, boat racing and school and cross country runs—he urged the necessity of dealing with such matters on statistical lines, and referred to the observations of Dr John Morgan in regard to the former and those of Dr Armstrong in regard to the latter He believed that if such rules as had been mentioned were adhered to and if boys the subject of asthma or valvular disease of the heart, and those subject to dyspnœa on moderate exercise were excused from runs the risk of injury from athletics was exceedingly small In conclusion he put to the meeting the question whether we do not often put the interests of the individual before the interests of the race, and urged the necessity of maintaining the sturdy character of the British race

Dr CLEMENT DUKES (Rugby) began by submitting that there were two points to realise—first, that terrible catastrophes did sometimes happen from unwise athletics, and secondly, that these were entirely preventable He insisted that injurious results could be obtained from severe rapid or prolonged exertion He referred to his own experience of the results of intemperance in exercise and claimed that for 27 years he had witnessed the powerful effects of injudicious running, but that since the remedies he proposed had been applied all injurious consequences had disappeared He contrasted the short, quick run which was liable to cause immediate damage to the heart which as rapidly disappeared with the long run from which permanent damage was likely to occur For full grown persons the short quick run was more severe and harmful in its effects He believed that running permitted of over exertion more in boys than any other form of exertion and confessed himself an unsparing opponent of unwise and unreasonable running He regarded it as most reprehensible for school authorities to allow active exertion immediately after meals and without an interval of an hour Other factors to remember were poor physique and distance and pace of running beyond the capacity of the boy He described three stages of the effects of too severe running first, an inability to continue breathing with comfort leading to quick shallow gasps, bright specks appeared before the eyes and the eye balls throbbed there were loss of power in the legs and inability to run straight In the second stage the boy ran mechanically and was completely dazed In the third, he staggered and fell, became insensible, and might die He had seen the heart enormously dilated during running and death had followed in three weeks In another case a boy died on the road during a run apparently from blood poisoning due to some toxin produced in the muscles He strongly emphasised the necessity for adaptation of the exercise to the age size and physique of the boys and for its effective control He also gave an account of the Rugby School runs and the precautions taken to avoid over exertion

Sir T CLIFFORD ALLBUTT confessed himself to be a disciple of Dr Clement Dukes in this matter He said that in regard to young men there was no single instance of permanent harm resulting from exercise unless during the previous months there had been some infectious disease, including under this heading a bad cold and true influenza

Sir T LAUDER BRUNTON had seen severe damage to the heart result and had taken a grave view of the effects of over exercise In company with several other people he had signed a letter to the *Times* newspaper, which had been much criticised, but which he did not regret, as he thought it had been a factor in bringing forward this discussion He believed that physical training was a good thing for mankind, good for mind and morals as well as for physique and he thought it should begin in the preparatory schools He compared the continental method, which was largely the practice of *gymnastic exercises*, with the English which was chiefly made up of games and he believed that the ideal for youths was a combination of the two He strongly approved a suggestion which had been made by Colonel Fox that there should be a games master at schools whose function it should be to supervise the games

Dr ANTHONY TRAILL, Provost of Trinity College (Dublin), gave his personal experience as an athlete with a remarkable record of active exercise up to a considerable age He also gave an account of his work as a Commissioner of Education in Ireland, and pointed out the importance in the primary schools of seeing that the children were properly fed He further pointed out the educational value of athletic exercises and their value morally as a physical deterrent from vice

Sir JAMES BARR (Liverpool) deprecated any suggestion of abolishing the factor of contest from games and believed that the more hazardous the game the better for the character of the individual

Dr [illegible] to boy [illegible] as we [illegible] examined 72 boy scouts and found that in 35 the heart was normal while in 37 there was some evidence of dilatation, 10 of them showing a considerable degree, with the impulse from ¾ to 1 inch outside the nipple

Dr A GORDON GULLAN (Liverpool) mentioned some cases under his own observation of damage to the heart after physical exercise He believed that physical exercise was good provided the man was trained up to the work he had to perform

Dr W J TYSON (Folkestone) pointed out the necessity of physical exercise in children before the school age and in men after the age of 30

Professor W OSLER and Dr W P KENNEDY (Bath) also spoke, and Dr BROOKS and Dr DUKES briefly replied

During the discussion the section adopted a resolution, moved by Sir LAUDER BRUN[illegible] SHAW (London), suggesting [illegible] British Medical Association [illegible] pronouncement as to the most suitable manner in which athleticism in schools may be so organised and controlled as to achieve the maximum of benefit and to reduce to a minimum any risk of harm to the individual schoolboy

At the close of this interesting discussion

Dr ALEXANDER DEMPSEY (Belfast) showed an unusual case of Argyria

Professor B MOORE (Liverpool) demonstrated a new method of administering oxygen, which had the advantage of economy and also secured that the patient breathed much more of the gas than by the ordinary methods

Dr CLIVE RIVIERE read a paper on

A Natural Experiment in Cardiac Strain

His observations were made upon 40 boys taken for a school excursion to a hilly district Of these 33 were healthy boys, but 20 of them were afterwards found to show enlargement of the heart of various grades which remained for weeks or months For comparison Dr Riviere examined the hearts of 181 average schoolboys between the ages of 10 and 14, and he showed diagrams indicating the results obtained He advised in regard to such excursions and to exercises in general that they should be mapped out with a view to the weakest members of the party that abundant sleep should be allowed, and that there should be short tramps with frequent rests between

Dr. FRANK C. EVE (Hull) read a paper on

A Case in which Pneumaturia was Apparently the Sole Indication of Glycosuria,

of which the following is an abstract. The patient was a man of 45 years who for four years had suffered from right ascending pyelitis due to the colon bacillus, with pus and often free gas in the urine and pain in the loins. No sugar was found in the urine. This sometimes kept him in bed for weeks at a time. He was given vaccine treatment (60–300 millions of colon bacilli every 10–14 days); this appeared to do good, but complete success was not attained until alkalies and an anti-glycosuric diet were adopted. This was advised on the supposition that there was in reality sugar in the urine which had been entirely converted into acid and gas by the bacillus coli. This assumption was verified (1) by the success of the anti-glycosuric diet, (2) by finding from his previous medical adviser that prior to the cystitis (seven years ago) he often had glycosuria. The patient now expressed himself as "quite fit," though there were still a few bacilli in the urine. There had been no albumin in the urine, from which (according to Adrian and Hann) the B. coli might manufacture gas. The patient's strain of B. coli could not be induced to produce gas in urine or liquid culture media, but would do so freely in gelatine media—a hint for which the speaker expressed his indebtedness to Dr. A. C. Houston. It was found that a standard bacillus coli [illegible] y from non-albuminous diabetic [illegible] 's organism approximated to the typhoid type in its feeble power of gas production. The patient so often complained of the smarting of acid urine that probably his sugar was often split up into acetic and lactic acids and alcohol without gas production. These irritating products would perpetuate the pyelitis and the sugar would nourish the germs it was desired to exterminate.

SURGERY.

WEDNESDAY, JULY 28TH.

President, Professor T. SINCLAIR (Belfast).

At the close of the discussion reported in our last issue Mr. G. P. NEWBOLT (Liverpool) read a paper on

Some Cases of Resection of Intestine.

In the case of the small intestine, he held that it was much better to resect than to return doubtful bowel in strangulated hernia; he had never regretted resecting bowel, but he had regretted returning bowel as to the vitality of which he had had some doubt. In the first five of his cases he had employed the Murphy button and he had found it of much service, and he still carried it in his operating bag, though he had not used it for some years. In all these resection operations it was essential to have plenty of room, and this could be obtained by extending upwards the incision. When the excision was not done for strangulated bowel he considered that a median incision was to be preferred, as the surgeon could not be certain in what part of the abdomen resection was needed. In resecting for malignant growths the ideal plan was to resect the bowel and to unite the ends at the same operation. For the small intestine he thought that end-to end union was the most satisfactory method, but for the large bowel lateral anastomosis was preferable. The paper was accompanied by a table giving particulars of 24 cases in which Mr. Newbolt had resected portions of intestine; in 11 of these the small bowel was affected and in 13 the large bowel.

Sir THOMAS MYLES (Dublin) expressed the opinion that immediate union of the bowel after resection for gangrenous hernia did not give the best results and this was especially the case in femoral hernia, where free enlargement of the wound was very difficult. He preferred to perform the operation in two stages, in the first he merely relieved the obstruction, laying open the bowel into the wound, and later he resected and joined the ends of the bowel. He was in favour of lateral anastomosis.

Mr. W. MCADAM ECCLES (London) pointed out that in a case of gangrenous femoral hernia the wound could not be sufficiently enlarged, and he was in favour of a separate incision. Which form of anastomosis was to be preferred depended on the individual case—for instance, if the proximal portion of gut was dilated and the distal portion was much contracted, end-to-end union would be very difficult, and in such a case lateral anastomosis would be preferable. He considered drainage of the neighbourhood of the union a valuable precaution.

Mr. G. A. SYME (Melbourne) stated that, when on opening a hernial sac he found the bowel to be gangrenous, he preferred to make a separate opening, by which he performed resection of the gangrenous portion and reunited the bowel, and then he returned to the hernial incision and completed the operation. He considered lateral anastomosis to be the best method of union.

Mr. A. B. MITCHELL (Belfast) was opposed to the temporary formation of an artificial anus. When operating for a tumour of the bowel and the patient was not in a condition to stand the complete operation he preferred to perform a lateral anastomosis and to drop the tumour back into the abdomen, and later he removed the growth. He considered lateral anastomosis better than end-to-end union.

Mr. C. P. CHILDE (Southsea) always completed the operation of resection of gangrenous bowel in one sitting. He had had seven cases, and of these six recovered and one died. He also did the resection in the hernial wound, using lateral anastomosis. The largest amount of bowel he had ever resected was 8 feet 9 inches in a case of gangrenous femoral hernia; the patient recovered from the operation and for a time did well, but she died from wasting six months after the operation.

Mr. W. THELWALL THOMAS (Liverpool) pointed out that in cases of chronic intestinal obstruction the patient was often not in a condition to stand a long operation; he preferred, therefore, to relieve the obstruction, and later he restored the continuity of the bowel, always employing lateral anastomosis.

Mr. NEWBOLT replied.

THURSDAY, JULY 29TH.

Demonstration of Cases.

Mr. A. B. MITCHELL showed two cases in which he had employed silk drainage for lymphatic obstruction. The first case was that of a man, 25 years old, who had had a chronic œdema of the lids of both eyes so that he was not able to separate the lids more than an eighth of an inch. Two silk threads were inserted and carried down under the skin of the face. The operation had been done a month before the demonstration and the œdema was greatly lessened so that the eyes could be opened more widely. In the second case œdema of the left cheek had followed extirpation of lymphatic glands of the left side of the neck. In this case also much improvement had followed the insertion of silk threads leading from the face to the neck. As Mr. Mitchell pointed out, gravity assisted the action of these artificial lymph tracts.

Mr. HOWARD STEVENSON (Belfast) showed a boy, four years old, who had numerous large subcutaneous lipomata of the abdomen and buttock; he had also great enlargement of some of the toes of each foot, apparently due to lymphatic obstruction. The conditions were hardly noticeable at birth, being seen for the first time when he was about three months old.

Mr. MITCHELL also showed a youth, 20 years of age, who had had extensive ankylosis after an attack of rheumatic fever. He had been unable to walk, as both feet had been in the position of equinus. Mr. Mitchell excised the astragalus on both sides, and the patient was able to put the foot flat on the ground and to walk with the aid of crutches. Excision of both elbows had given him very useful arms

Sir WILLIAM MACEWEN (Glasgow) opened a discussion on

Modern Methods in the Treatment of Tuberculous Disease of Joints.

He commenced by saying that the surgeon would have very great difficulty in deciding on the best treatment of a case if the particular variety of tuberculous joint present had not been settled. The stage also of the disease must be borne in mind, for the treatment fit for one stage might not be equally suitable for another. If the tubercles in the joint were grey and discrete and the vascular supply was good, it was possible to influence these tubercles through the blood stream, but when the tuberculous tissue had undergone caseation and the vascular supply of the part was diminished this form of treatment was no longer applicable. When it was possible it might act either by throwing out a barrier which prevented the further progress of the disease, or by might produce absorption. When the tuberculosis had spread from the bone under the articular cartilage, so as to throw it off, the joint must become stiff if it was to heal; the question then arose, Was it better to treat this by fixation or to open and remove as much of the tuberculous tissue as possible? In the earlier stages was it wise to let the joint become stiff with the risk of liquefaction of the tuberculous deposit? In deciding this question it must be borne in mind that many other tissues suffered in addition to the joints—for instance, the muscles; there was in many cases an ascending trophic neurosis. If the joint was one, such as the knee, where ankylosis after excision was certain to occur, it might be left much longer without operation than a joint where excision might be followed by movement, as in the elbow. The surgeon must determine whether the bone or the synovial membrane was affected or both. The patient was not often brought to the surgeon at a very early stage when the bone only was affected, but if seen in this stage operation was advisable. If the disease in the bone could not be reached without passing through the synovial membrane, the operation should be done in two stages; at the first the synovial membrane was opened and the cavity of the joint was shut off by sutures, and at the second operation the disease in the bone was removed. Then iodoform and glycerine emulsion was introduced and care should be taken to leave some of the emulsion along the margins of the incision so as to prevent infection. Iodoform was most effective before caseation had occurred. Subnitrate of bismuth with vaseline was useful, but iodoform was better. Bier's congestive method was of value at an early stage, but not unaided. When the synovial membrane was thickened the parenchymatous injection of iodoform emulsion was useful. To obtain the best results with iodoform the crystals should be large and then toxic effects were hardly ever seen. A very useful preparation was made with one part of iodoform and four of boric acid; the boric acid served to dilute the iodoform. In the later stages, when the articular cartilage had been thrown off and large masses of tuberculous granulation tissue were present, the question of excision must be considered, even in children. Excision should not be done in the typical manner described in books; for instance, in the case of the hip the neck of the bone *should never be removed, but the whole operation should be* intracapsular. The surgeon should not wait until sinuses formed before he excised. The time for excision had come when the cartilage had been destroyed. As in the case of children we wished to preserve the growth of the bone, the excision should never reach to the epiphyseal line. It must not be forgotten that the removal of tuberculous foci often greatly improved the general health.

Mr. ROBERT JONES (Liverpool) also read a paper introductory to the discussion. He claimed that tuberculosis ran a different course in the child and in the adult. In the child the disease was almost benign and tended towards recovery; in the adult it was much more serious, and excision was often needed. In children excision if done early often led to useless limbs. The early diagnosis of tuberculosis in the child was often important. The action to the new tuberculin was trustworthy; an injection of from three to five milligrammes between the shoulders was sufficient. X rays were of little use in very early cases. *The most valuable early sign was rigidity, preventing move*ment of the joint in all directions. It might be laid down that if there were no rigidity there was no arthritis, no anæsthetic being employed during the examination. Limitation of movement in one direction was not of much value; the rigidity must be towards movement in all directions. Pain was neither a constant nor a valuable sign. It was often difficult to determine when treatment might be discarded; the best indication was when the range of movement was not influenced by use, or when, if ankylosis was present, the position of the limb did not vary. The most important factor in the healing of tuberculous joints was open air; day and night, if possible, the child should be out of doors. Any splints employed should b[illegible] the simplest type. If the tuberculosis affects the [illegible] the patient should lie on a convex couch. The [illegible] should be over-extended in tuberculosis. The ankle should be fixed so that the heel should be the first part to touch the grou[illegible]loped they should be [illegible] symptoms, for many [illegible]bscess approached the surface the contents might be drawn off through a very small incision Should an abscess become septic, with a rise of temperature, it should be opened early. For paralysis from spinal caries no operation was needed, as recovery occurred spontaneously in 97 per cent. Mr. Jones was in favour of reducing deformity of the spine due to caries at whatever stage it might be seen. In osteotomy of the femur he was in favour of *doing it in two stages*, dividing two-thirds of the bone at the first operation, and two weeks later fracturing the bone when the skin wound had healed. In cases of angular ankylosis in the adult it was possible to estimate the prognosis thus. Supposing the angle is 15°, the splint was made of an angle of 20°; then if more move[illegible] but if the [illegible] that dise[illegible] governed by opsonic estimations, were sometimes of value. Bier's congestive method was sometimes useful, but occasionally the results had been disastrous.

Professor SONNENBURG (Berlin) commenced by saying that within recent years operations had been less frequently performed for caries than before He had tried Marmorek's serum and the results were sometimes good. He had employed the new tuberculin of Koch in 20 cases with much benefit. It might be employed for the local skin test. For treatment at first only very weak solutions were employed for injection. One milligramme of the tuberculin was injected, and if no reaction the dose was increased up to 8 or 10 milligrammes or until a reaction occurred. The temperature in a satisfactory reaction might not exceed 38° C., but it might rise to over 40° C. If a reaction occurred an interval of some days was left and then the injections were recommenced, beginning with a smaller dose than that which had caused the reaction. After every reaction the skin test was employed before treatment was recommenced. The injections were best given on the chest or back; they usually caused some pain. A cupping glass might be used for 20 minutes immediately after an injection. Should a rigor occur after an injection it might probably mean that there had been an injection into a vein Tests for antibodies should be made from time to time. The treatment must be continued for months or years.

A paper on the subject by Mr. A. H. TUBBY *(London)* was read by Mr. W. THELWALL THOMAS (Liverpool). The tuberculous focus might in some cases be extra-articular, and the question whether the joint would be implicated depended greatly on the relation of the epiphyseal line to the joint, and so some joints were much more early infected than others. A para-articular abscess generally formed on one side of a joint; it caused pain especially after exertion, and a special tender spot could be found; thickening followed, and later still the joint might be affected. The treatment would be rest at first, but the abscess should be opened early.

Dr. J. CRAWFORD RENTON (Glasgow) considered that the diagnosis in early cases had been helped by X rays and by Calmette's tuberculin test Bier's method was useful, and the injection of tuberculin every 14 days was also of value. Good food and open-air treatment were of great importance. Extension was useful, and a coxa vara splint causing abduction was very good for cases of hip disease. He believed that many early cases did not need operative treatment. In the advanced stage in young people extension and fixation in plaster-of-Plaster were of great value, but excision might be needed when other means failed. After excision the limb should be placed in an apparatus for 18 months to prevent deformity Operation should not be delayed in the case of the elbow-joint, and care should be devoted to the after-treatment. In adults operation was more often needed, and after excision of the knee the femur and tibia should be pegged together In cases of deformity of the knee-joint with quiescent caries he advised operation, and later the use of an O'Connor's extension boot gave an excellent functional result.

[illegible] had often found the [illegible]

He practised partial excision only in well limited cases.

Mr. S. MAYNARD SMITH (London) described a series of 34 cases in which tuberculosis of bones or joints had been treated by vaccines, and of five treated only by inoculation four were cured; of 12 treated by operation before inoculation

11 were well, and in seven of these there was complete restoration of function. He also described a method by which auto-inoculation was employed for diagnosis and also for deciding when the disease was cured. By means of massage, or by walking, or by Bier's bandage, some of the toxins were forced into the circulation, and gave rise to a reaction. He considered the method to be of great value.

Mr. W. RUSHTON PARKER (Liverpool) spoke strongly in favour of the Thomas's hip-splint in the treatment of tuberculous hip. He looked upon it as the most successful method of dealing with this condition.

Mr. C. W. CATHCART (Edinburgh) claimed that it must be acknowledged that tuberculosis was a curable disease. He had employed Bier's congestion method for some years with great success. Iodoform and glycerine emulsion were of value; and for treating tuberculous abscess he preferred to inject them with the emulsion after drawing off some of the contents. The practical difficulties in estimating the opsonic index interfered greatly with the use of tuberculin.

Sir WILLIAM MACEWEN, in reply, said that in the great bulk of children tuberculosis of a joint began in the epiphyses and not in the synovial membrane; and it must be possible to evacuate this disease before it invaded the joint. Rigidity was of value as a test for tuberculosis of a joint, but the disease was sometimes present without any rigidity. The functional results after excision depended greatly on the manner in which the excision was done; for instance, in the case of the shoulder it was important not to turn the long tendon of the biceps out of its groove. An important factor in the treatment was fresh air. God had given us fresh air, but as soon as lofty hygienic rooms were built they were taxed more heavily than small, low, unhygienic rooms.

OPHTHALMOLOGY.

WEDNESDAY, JULY 28TH.

President Dr. JOHN WALTON BROWNE (Belfast).

The PRESIDENT extended a hearty welcome to all those who graced the busy and enterprising city of Belfast with their presence, and after warmly welcoming the section and thanking his colleagues for his election expressed the deep regret that they all felt for the loss which the Association, and their section in particular, had sustained in the death of Mr. Simeon Snell. But his work lived with them, for no one had done more than he to put the subjects of nystagmus, especially that affecting miners, and the injuries caused to the eye by foreign bodies on really scientific bases. As regards their own work at Belfast, he had only to mention the work of McKeown to remind them that new and important methods of treatment had been initiated with them. McKeown first used the method of washing out remnants of cataract; and he was the first in the United Kingdom, perhaps in the world, to insert a magnet into the human eye to extract steel fragments. Lastly, McKeown was the first to insist on the necessity for a special examination in ophthalmology before candidates should be eligible for graduation in medicine. At the present time there was some conflict of opinion as to the relation of eye specialism to other special departments, the ear, nose and throat. He would remind them that eye and ear had in the past been commonly associated in practice; the founder of Moorfields Eye Hospital had practised in these two branches. It was the custom in most parts of Ireland for the four departments to be worked together. Whatever might be the ultimate trend of practice he felt sure that no man could be really competent as an eye surgeon who could not for himself examine a nose and be sure that complications of the lacrymal sac did not have their origin in the nasal chambers.

Dr. A. FREELAND FERGUS (Glasgow) opened a discussion on

Eye Injuries in their Relation to the Workmen's Compensation Act.

He said that the opener for this discussion had been selected in the person of Mr. Simeon Snell, and it was a matter of deep regret that his wide personal knowledge of this subject was no longer their valued possession. He felt that the problem of compensation for eye injuries was an all but insoluble one, at any rate in our present state of knowledge. The statistics at present available for examination were insufficient for any safe conclusions to be based thereon. Attempts had been made to derive mathematical formulæ expressive of what might be called visual efficiency. The works of Berry of Edinburgh and of Percival of Newcastle-on-Tyne were invaluable, and none could doubt that these two men were the highest of authorities in the department of mathematics as applied to the practice of ophthalmology. But with their full knowledge of these matters both had been careful to state that no formula could be absolute; at best it could only express an approximation or perhaps indicate the directions in which a solution was to be obtained. So great an authority as Professor Peter Guthrie Tate was reported to have said that it was quite impossible to formulate anything which involved human volition. He might go a step further and say it was impossible to reduce to mathematical formulæ anything involving human action based on individual human volition and intelligence. For example, he had known a blind man who could scarcely find his way to the house next door and yet another who could play an excellent hand at whist. On the performance of which of these two men were they to found a rigid basis for formulation? In every case there was, besides the determination of visual acuity, the more important determination of intelligence, and since that varied with every man, so their estimation of the seriousness of any given injury was almost individualistic. From his experience he would conclude that all forms of work might be roughly divided into two groups. 1. That in which visual acuteness was of primary importance. To this class belonged such occupations as those of watchmakers, authors, lawyers, doctors, and many others. For most of these good binocular vision was an absolute necessity. 2. In the other class visual acuteness in the strict sense of the term played a secondary part. Efficiency in the work depended more on the light sense and in the sense of alignment. To this group belonged most manual and labouring work. And in these cases it became a point for consideration whether a man in such employment must have binocular vision. Dr. Fergus proceeded to cite trades in which men with single-eyed vision successfully performed their tasks, and argued therefrom that binocular vision was not necessary provided that they possessed a good light sense and a good sense of alignment. It therefore would seem that any attempt to express visual efficiency in terms of visual acuteness alone would lead to serious error. He then proceeded to expound an experiment which went to prove that a man could possess a sense of location sufficient for such an employment as riveter provided he retained these two factors of vision, light and alignment. The power of appreciating distance by convergence was lost, but there remained the subtle factor of the accommodation. There were, however, other points to be considered. 1. The new condition might necessitate the man changing his work. 2. The loss of an eye might effect his chance of getting other work. There was no doubt that the work of a one-eyed man was limited, and if this limitation affected a man then compensation should be liberal. A man could not profitably change his mode of life at adult age. It was no use to cry "back to the land" to the adult slum dwellers, the work of migration must be begun with the children. So it was with every form of work, the new hand was less efficient than the practised hand. It was therefore the more important that they should ascertain those branches of labour in which a one-eyed man could work, so that those of these trades, and those of other trades, could be readily distinguished in the matter of compensation. Secondly, they had to make up their minds on the point of the justice or otherwise of extending compensation to the prospective disabilities of an injured man. Many judges had held that this was too remote. They seemed to think that if a man recovered from his injury, and it were proven that he was able to work, there the matter ended, and that he was not entitled to compensation for future contingencies which were only problematical. Yet it could not be denied that at the present time a man so situated had less chance of getting work than a normal man. He was held by insurance companies to be more liable to risk of injury. He felt that for such cases as these there was no help but the institution of a "contracting-out" clause. The Act as it stood was good in intention, but these good intentions were tending to work out as a serious handicap to those who were not of strictly normal physique, and destitution was being fostered by the very Act that was devised to prevent it. It ought not to pass the wit of man to frame such an amendment to the provision of the Act that would not open the door to abuses.

Lastly, he wished to draw attention to the view held by workmen on the intentions of the Act. They had the idea that it was an insurance scheme, and when injured they at once thought of what they would get out of the injury. It was not so; the Act was intended to prevent loss by injury, and this proper idea was being lost to view by those most affected.

Dr. CECIL E. SHAW (Belfast) in dealing specially with the unsatisfactory working of the Workmen's Compensation Act with regard to compensation for the loss of an eye said, according to the Act, no compensation was given for such loss but only for partial or total incapacity for work. Where one eye was lost and the other was healthy a man soon learned to work with one eye and in the great majority of cases work could be done quite as well as before. He knew of four men in Belfast who were daily driving motor cars, in spite of having lost an eye, and one of them, a professional chauffeur, told him that six months after the accident by which his eye was lost he had forgotten all about it. According to the strict interpretation of the Act, such cases should only obtain compensation for the few months that elapsed before they were fit to work again But the true injury in loss of an eye was not generally any loss of capacity for work [illegible] of total blindness owing [illegible] eye. Everyone was liable [illegible] the one-eyed man it was a much more serious event than to the man who had another eye to depend upon. Owing to this many employers avoided one-eyed men, since a slight accident to one eye might totally incapacitate them. Even though perfectly fit for work, they might fail to obtain it on this account. An interesting case occurred in his experience a short time ago of which the facts were briefly as follows. A working girl lost an eye by accident, and after some months' incapacity, for which she received compensation, she returned to her work, which she was able to do efficiently. But when slackness of work arose, and she had to seek work elsewhere, she could not get a job on account, as she believed, of her being one-eyed. She then brought an action for compensation, but it was pointed out that there was no ground to go upon since there was no incapacity, as proved by her having worked at full wages for some months after the loss of the eye. A better form of compensation for the loss of an eye would be a sum fixed according to the average wages, to be paid irrespective of all theories or statements about a workman's capacity for work. The endless litigation involved [illegible] cases benefited the great learned professions, no doubt [illegible] cost of the litigation came.

Dr. W. HERBERT BRAILEY (Brighton) said that one of the vicious tendencies of the working of the Act was to assign any disease affecting a workman to the direct influence of his occupation. No tendency could be more injurious. The only way of escape from this was the preliminary examination of workpeople to ascertain their fitness or otherwise for the particular work they intended to follow.

Mr. BISHOP HARMAN (London) said that he was surprised at the comparative indifference exhibited by the openers of the discussion to the loss sustained by a man on the one point of deprivation of binocular or stereoscopic vision. It seemed to him that in many of the tasks mentioned, even such a one as bricklaying, the sense of the position of things was immeasurably better with the two-eyed man than with the one-eyed man. He would ask them to try an afternoon's round of golf with one eye obscured, and see how they were "off" [illegible] was perhaps of the [illegible] there were men who [illegible] he had known men successfully working for years as engineers and fitters with a single eye, but they did not present the average, and one might ask how much better workmen might they not have become had they retained both eyes. Next there was the point of loss of nerve power—pluck. It was without doubt of great importance in the modern workshop filled with rapidly moving machinery. If a man lost skill in a game because of a serious accident in that kind of game, and of this he had reason to be sure, how much more in a machine-shop? Then there was no doubt that the one-eyed were seriously handicapped in getting work. He found that insurance policies for domestic servants excluded one-eyed persons from the current rates. Perhaps they would remember the evidence of a trial which showed the lengths of deception to which a girl was brought who was persuaded by a rogue that he could make a new eye grow for the one she had lost! Hope to retrieve her lost position led her captive in his snare. There could be little doubt that they were right in urging employers to examine their workpeople: it was good for both parties. Disputes about the former states of injured organs would be eliminated and work fitting to the capacities of the men would be apportioned. Lastly, he felt that the most pressing need was the removal of these cases from the grasp of the lawyer. The waste and bitterness following their operations were notorious. He would like to see the establishment of "Accident Courts." To the presiding judge of every such district court reports of any accident should be *compulsory at the time of the accident, together with the* facts of the condition as ascertained by the medical men representing man and master; these reports, together with their final reports, should form the material on which the judge should award compensation in any case where he deemed it was due. Advice he might call in, but argument would be excluded and the bane of litigation checked.

Dr. ARTHUR GREENE (Norwich) said that he was inclined to agree with Dr. Fergus in considering that the individual who has lost vision of one eye was not (except for a few special occupations) at any great disadvantage from an earning point of view, provided the remaining eye had good vision. Many people (including the speaker) had little or no sense of perspective, and the loss to such an individual of one eye was only the limitation of the field of vision. He felt that any satisfactory scheme of legislation must take particular cognisance of the likelihood of the injury to affect the freedom of the sufferer to obtain work. He cited the case of a nurse-girl on whom Mules's operation had been done with such success that she passed as a two-eyed girl, but when her mistress found out the true state of affairs she at once lost her situation, although no fault could be found with her work.

Dr. R. WALLACE HENRY (Leicester) said that there was a great need for the reduction of lawyers' costs. He strongly advocated bringing together the medical men of the two sides in cases of dispute. They could at least agree on the facts of the condition, in eye cases at any rate, and agreement on these points narrowed the issue to one of opinion as to future events. He strongly supported Dr. Shaw in his remarks on the difficulty which one-eyed people had in getting work.

Dr. S. JOHNSON TAYLOR (Norwich) asked if it was supposed that a man of 40 to 50 years could take up fresh work when injury prevented him from doing work that required binocular vision. He was strongly impressed with the view that even good bricklaying wanted two eyes. He cited the case of a friend who could at one time always beat him at the game of bowls, but who never beat him again when by reason of a retinal hæmorrhage he lost the use of one eye.

Professor EMILE FUCHS (Vienna) said that this was not a purely scientific question. It could not be denied that most one-eyed men were capable of work, but the difficulty lay in the conflict of the interests of employer and servant. An employer did not want a one-eyed man because of the added risk of injury. This had to be met by legislation. In Germany and Austria no personal responsibility lay with employers to provide compensation. There was a fund to which all employers and men subscribed by way of insurance; 90 per cent. was provided by the masters, 10 per cent. by the men. This public fund was administered by their own judges at the instance of their own medical men, and the sole idea was that of doing justice to the injured man.

Mr. G. A. BERRY (Edinburgh) said that the difficulty of estimating in the influence of injury upon pre-existing disease was such that medical examination of workpeople was urgent. He did not agree in the seriousness of the added risk of injury to one-eyed men. So far as compensation could take cognisance of any such problem, it should only extend to six months after the injury to allow for the strangeness of the conditions, but more might be done for young people whose whole career might be altered.

Dr. JOSEPH NELSON (Belfast) said that the facts of eye injuries were so precise that there could be no room for taking sides. He thought that medical men should combine against the practice in vogue of setting them one against the other in giving evidence.

about one in several hundred—showed Altmann's granules, distinguishable by their red colour from the brown granules of melanin. In the case of small round cell sarcoma, in which the cells otherwise resembled lymphocytes, there was a marked absence of granules as compared with lymphoid tissue. (5) Endothelioma.—Granules were small and few in number in one of this group of cases and absent in three. In the remaining instance, however, granules were numerous; this was a case of perithelioma in which islets of tissue, well-staining as regards both nuclei and granules, were embedded in a groundwork of necrotic tissue. Conclusion.—The investigation of the question under discussion was still incomplete. The group of sarcomata was very inadequately represented owing to lack of fresh operation material, and Dr. Beckton would be greatly obliged for any kind assistance in this respect. Granules, again, had been found in cells of new growths of doubtful or limited malignancy, and might prove to be of special interest in these cases. But as far as the present investigation has proceeded the conclusion might be drawn that "in malignant new growths granules tend to disappear, or to be absent altogether, from the particular type of cell involved"; and the cells of malignant neoplasms showed an important histological difference from cells of normal type; this difference might be regarded as an expression of deviation from, or loss of, normal function. Dr. Beckton concluded with a request for fresh sarcomatous material to be sent to him so that it reached him not later than 24 hours after removal from the body, either simply wrapped in oiled silk without the addition of preservative, or, if preservative were used, formol-Müller should be the one chosen.

In the discussion that followed Dr. W. S. LAZARUS-BARLOW (London) pointed out the importance of Dr. Beckton's observations, which for the first time placed upon a scientific basis the accurate differentiation between normal and cancer cells on the one hand, and between sarcomatous and purely inflammatory tissues on the other. The observations had a further value, in the speaker's opinion, in that the appearance of Altmann's granules in plasma cells and lymphocytes afforded a very delicate index of the comparative efficiency of various methods of fixation, for it seemed obvious that Dr. Beckton's observations pointed in no uncertain manner to essential chemical differences in the molecular constitution of cell granules, which when fully studied would, it was to be hoped, lead to a practical system of classification. Dr. Lazarus-Barlow further suggested that the granules of plasma cells and lymphocytes might possibly be zymogenic in function—in other words, that these cells were true secreting glands—in which case the whole question of internal secretion would command increased attention.

Dr. A. E. MOORE (Cork) contributed the observation that sections of myxoma fixed in 5 per cent. formalin, cut with a freezing microtome and stained with carbolic thionin blue, showed a large number of plasma cells filled with dark staining granules, whilst the other connective tissue cells showed no granules whatever.

Professor I. WALKER HALL (Bristol) pointed out the importance of determining the existence or absence of Altmann's granules in the cells of fœtal tissues in view of the possibility of their marking a stage in cell development.

After Dr. BECKTON had replied to some inquiries as to methods of technique from Professor J. LORRAIN SMITH (Manchester) and others, the section passed to the consideration of

Some Observations on the Pathology of Innocent Goitre,

a subject introduced by Dr. HELEN CHAMBERS (London), who illustrated it by an extensive and comprehensive series of lantern slides dealing with both the naked-eye and microscopical appearances of material obtained during a study of 261 cases of goitre treated at the Royal Free Hospital in the nine years from 1900–08. As Dr. Chambers's object had been to study the pathological changes in the thyroid gland in cases of innocent goitre, those cases only were considered which had been treated by operative removal, and of these 93 had been examined histologically. Excluding malignant disease and Graves's disease, three types of goitre were recognised—viz., parenchymatous, adenomatous, and adeno-parenchymatous. Parenchymatous goitre must be distinguished from the other forms for the following reasons: 1. The macroscopic changes in the gland were distinct. The whole gland was affected uniformly; there were no encapsuled masses and the tissue had no tendency to break down or form cysts of large size. 2. It was a condition occurring almost exclusively in young adults. 3. In comparison with other forms of goitre, cases of this type rarely needed surgical interference. In a total number of 261 cases 30 only were of this variety. 4. The marked tendency of goitre to affect women was much less evident in this form. During the years 1900–07, 21 cases were treated, 10 males and 11 females. The second and third types of goitre—viz., adenomatous and adeno-parenchymatous—were probably closely related, and were characterised by the development in the gland of encapsuled masses. In the adeno-parenchymatous form these were in large numbers, and were associated with increase of the gland tissue. In the adenomatous form the enlargement of the thyroid was due to the growth of one or more encapsuled tumours and the gland tissue was but little affected. The cases in each group were arranged in quinquennial age periods, and the relative age liability at each period was represented graphically. Before referring to the histological structure in the goitre cases, the results of the histological examination of thyroid glands from 60 consecutive post-mortem cases were considered. The changes in adults were comparatively slight; in children under two years the appearance of the gland was often much altered. The colloid disappeared, the vesicles became filled with cells, and the whole gland became a solid cellular organ. Half of the thyroid glands of children under two years were in this condition—i.e., in cases of tuberculosis, empyema, broncho-pneumonia, and acute nephritis. The other changes of importance were those which sometimes followed injury to the gland, as in tracheotomy. The vesicles had a similar appearance to those in Graves's disease. They were tubular, almost empty, had infolded walls, and were lined by high columnar epithelium. The histological structure of the goitre cases was considered in two sections: (1) the structure of the adenomata; and (2) the changes found in the gland tissue. 1. 70 adenomata had been examined; one-fourth of these had a structure closely similar to that of the thyroid in an early fœtal condition. The other cases were either similar in structure to the adult gland or the vesicles had become very large and cystic. Fœtal adenomata had been found in a few cases in very large numbers and extremely small. They could be recognised when 1 mm. and 0·4 mm. in diameter. 2. The changes in the gland tissue were of chief interest in relation to the possible connexion between so-called primary and secondary Graves's disease. Four illustrative cases were described in detail. The conclusions drawn were: 1. That the condition of the vesicles in some forms of inflammation such as followed a tracheotomy wound might be identical with that in cases of Graves's disease. 2. That primary Graves's disease was occasionally found associated with changes in the thyroid which were focal in character. 3. That in forms of goitre other than Graves's disease—viz., adenomatous and adeno-parenchymatous—the presence of nervous symptoms was commonly associated with the occurrence of histological changes in the thyroid gland tissue, consisting of local accumulations of round cells and alterations to a more or less extent in the surrounding vesicles. 4. In certain forms of goitre the histological characters were such as to suggest a diffuse chronic inflammatory condition—viz., marked plasma cell infiltration and endarteritis; in other cases similar changes were found in localised areas. Many attempts had been made to find evidence of organism infection, including bacteriological examination of the tissue and animal inoculations. The results had been entirely negative. The histological characters at any rate suggested a toxic substance in the gland—in some cases diffuse, in others localised. As to its nature and origin they were at present entirely in the dark.

The PRESIDENT, Professor J. LORRAIN SMITH (Manchester), and Mr. J. GRAHAM WILLMORE (Gabel el Tor) briefly discussed Miss Chambers's conclusions, the last-named pointing out the advisability of examining the stools of all cases of endemic goitre in view of the fact that amœbæ had so frequently been demonstrated in the fæces in epidemic goitre.

The PRESIDENT then vacated the chair, which was occupied throughout the subsequent proceedings by Dr. A. E. MOORE, Vice-President of the Section.

Dr. LAZARUS-BARLOW demonstrated the entire series of lantern slides illustrating the skotographic experiments which formed the basis of the Goulstonian lectures before the Royal College of Physicians of London, which have already been reported in THE LANCET.

Dr. LAZARUS-BARLOW replied to some questions from Professor A. R. FERGUSON (Cairo) and Professor LORRAIN SMITH.

Mr. CECIL W. ROWNTREE (London) read a paper on

X Ray Carcinoma,

illustrated by numerous lantern slides. This paper was based upon Mr. Rowntree's Hunterian lecture, which we published in our issue of March 20th, p. 821.

Professor LORRAIN SMITH demonstrated some museum preparations of stomach, liver, and lung from an interesting case of

Cancer of the Pylorus,

in which the patient, a woman aged 35 years, had developed respiratory symptoms accompanied by foul expectoration during the latter part of her illness. Post-mortem examination showed the existence of a large carcinoma occupying the mucous membrane and walls of the pyloric orifice; the diaphragm was covered with flat scale-like deposits; in the liver were a few small secondary nodules; the retro-peritoneal glands in the lumbar region were enlarged; and a small mass of cancerous growth was found in the pouch of Douglas. The lungs were uniformly invaded by new growth in the form of columns of cells occupying the lumen of the lymphatics to such an extent that their presence could be traced over the pleural surface as a delicate meshwork of yellowish lines outlining the lobules, and on section of the lung as small yellow points. Microscopical sections, of which photographs were shown, demonstrated the presence of mucoid degeneration of the cells of the original tumour. In the lung, on the other hand, an excessive number of cells loaded with globules of myelin were found in the alveoli. In sections of the bronchial glands myelin could be seen in the stroma of the glands, but none in the enclosed areas of lymphoid tissue—points which were well brought out in the lantern slides of the photo-micrographs taken by the aid of polarised light.

THURSDAY, JULY 29TH.

In the morning this section joined forces with the Section of Hæmatology and Vaccine Therapy in the surgery class-room, under the joint presidency of Sir ALMROTH WRIGHT and Professor SYMMERS, for the purpose of discussing

The Early Diagnosis and Treatment of Tuberculosis,

and an account of the morning's proceedings will be p [illegible] e T. [illegible] d [illegible] tion of Blastomycetes and Cancer and the effects of antitoxic serum upon experimentally produced cancers was given in the pathological museum by Professor SANFELICE (Bologna).

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 28TH.

President, Dr. T. OUTTERSON WOOD (London).

The PRESIDENT opened the section with some introductory remarks on the subjects and papers selected for discussion. He then pointed out the relationship of the specialty to general medicine. At one time the study of mental diseases was looked upon as something apart from the subjects considered necessary in the medical curriculum, and he well remembered the almost exclusive nature of the study of psychological medicine when he first became connected with asylum work over 40 years ago. Fortunately, the subject was now taught and included as compulsory in all examinations for medical qualifications. The fact of having a section assigned to them could not fail to be advantageous to the study of mental diseases and tended to keep up the medical spirit in asylum work. The promotion of a closer connexion between psychiatry and neurology [illegible] a matter well deserving atten- [illegible] overlapping in these subjects [illegible] consider the advisability of extending the scope of the section so as to make it include these two kindred subjects. There was in the study of insanity, quite apart from that of asylum administration, so much medical work which trenched closely upon and in many instances included neurological problems that it could not fail to be to the mutual advantage of the students of both to have these two subjects combined in one section.

The following resolution was proposed by the PRESIDENT and seconded by Dr. D. G. THOMSON (Norwich):—

That in the [illegible] bjects of [illegible] and the [illegible]

A second resolution was proposed by Dr. W. R. DAWSON (Dublin) and seconded by Dr. M. J. NOLAN (Downpatrick):—

[illegible] authorities of [illegible] University of [illegible] establishing [illegible] lical faculties [illegible]

A third resolution was proposed by Mr. G. R. LAWLESS (Armagh) and seconded by Dr. T. D GREENLEES (Streatham):—

That this section desires to express its approval of the principles of the Asylum Superannuation Bill now before Parliament.

These resolutions were carried with instructions that they be forwarded to the Council of the Association for consideration.

Dr. J. M. MACCORMAC (Belfast) read a paper on

The Superficial and Deep Reflexes as an Additional Means in the Diagnosis of the Principal Forms of Mental Diseases.

This subject, so far as he was aware, had not received attention in this country. The conclusions he had arrived at after careful observations for many years were much in harmony with those of Agostini. 1. He first reverted to the subject of *crossed knee-jerks* If the patellar tendon on one side were struck the opposite leg would be adducted mainly by the action of the crureus and vastus internus, which muscles were seen to contract even when the movement was slight. This patellar jerk was a true reflex, and he had observed in certain forms of sclerosis of the spinal cord that a slight percussion would cause the knees to knock together and at the same time the arms were adducted. These actions soon lessened and passed into a state of tremor which gradually disappeared. 2. His observations on the superficial and deep reflexes in their relation with the modification of painful sensibility in mental disorders had shown him that it was possible to establish some formulæ which corresponded in a general way to the state of the reflexes in each of the principal forms of mental disorder and which, in consequence, were not without value in the diagnosis of these affections. In *general paralysis of the insane* the condition of the reflexes varied in the different stages of the disease. In the initial stage of this disease there was generally a weakening of painful sensibility and of the cutaneous reflexes with the exception of the plantar reflex. On the other hand, the deep reflexes were exaggerated. In the second stage of the disease the plantar reflex was very markedly exaggerated, and all other reflexes, both deep and superficial, were increased; the tendon reflexes were still more marked than in the first stage. In the third stage of the disease all the reflexes became weaker until they finally disappeared. During an epileptiform attack the superficial reflexes were decreased or abolished, but the tendon reflex was exaggerated and often accompanied by fibrillary contractions, which might be transmitted from a limb to the trunk and then might pass to the limbs of the opposite side. In *epileptic insanity* sensibility to pain as well as the reflexes produced by stimulation of the skin and mucous membranes were generally lessened. On the contrary, the tendon reflexes were normal. After some convulsive attacks the tendon reflexes were increased, whilst the cutaneous reflexes were considerably weakened with the exception of the plantar reflex, which was augmented, and might be associated with trembling or even with epileptoid movements of the foot. *Hypochondriacs and neurasthenics* generally presented an increase of all reflexes, both superficial and deep. In *hysteria* there was a decrease of painful sensibility and of the cutaneous reflexes. In *alcoholic paralysis* painful sensibility and tendon reflexes were exaggerated, whilst the cutaneous reflexes (except the plantar reflex) were weakened. In *acute mania* the reflexes were normal. In *secondary dementia* all reflexes were exaggerated. In *melancholia* painful sensibility and cutaneous reflexes were normal, whilst the tendon reflexes were exaggerated. In the stage of melancholic stupor painful sensations, which on superficial examination might appear feeble, were in reality normal; the cutaneous reflexes were feeble; the tendon reflexes were exaggerated. The above statements showed how employed was that introduced by Mr. Barker, and he felt strongly that it was the best. By the use of a fluid heavier than cerebro-spinal fluid one had definite control over the distribution of the analgesia. He advocated a preliminary injection subcutaneously of a weak solution of cocaine. In this way the subsequent intra-spinal injection was rendered painless. Spinal anæsthesia was useful in preventing shock. In very nervous persons he was in the habit of employing spinal anæsthesia in the usual way, and later of giving in addition just so much ether, by the open method, as would obliterate consciousness. He considered this combined method of great use in nervous persons and in cases where great shock was feared, as in amputation through the thigh or disarticulation at the hip-joint.

Dr. G. A. H. BARTON (London) was convinced that the merits of spinal analgesia could not compare with those of general anæsthesia. In a considerable percentage of cases failure to produce analgesia occurred. The after-effects, both immediate and late, were serious. In the majority of cases the retention of consciousness was a drawback. In a few cases, as in the regurgitant vomiting of intestinal obstruction, it was an advantage, because it made inhalation of the vomit impossible. He believed that the proportion of deaths was as high as 1 in 500, and this was to an anæsthetist an appallingly high figure. He believed that in the future the use of spinal anæsthesia would be confined within very small limits.

Mr. C. A. LEEDHAM-GREEN (Birmingham) gave particulars of his four and half years' experience with spinal anæsthesia. From the surgeon's point of view the anæsthesia was perfect In his own practice he had seen little of complications and after-effects and the headache was usually quite trivial and transient. It was a great advantage that the patient could be given liquid nourishment at once.

Dr. V. G. L. FIELDEN (Belfast) believed that the greatest drawback to the use of spinal anæsthesia lay in the impossibility of altering the dose. Once the fluid was injected it was impossible to get it out. Yet it was usual, in inducing general anæsthesia, to find that two successive cases required widely different quantities of the drug.

Professor W. E. DIXON (Cambridge) said that he had made use of intraspinal injections only in animals. He suggested that some of the unfortunate after-effects might be due to leakage of cerebro-spinal fluid from the spinal theca rather than to the direct effect of the drug. He thought that the paralysis described was probably peripheral in origin and not due to changes in the spinal cord.

Mr. CHIENE replied.

Mr. A. E. BARKER (London) read a short note upon the

Elimination of Stovaine after Spinal Analgesia.

Before spinal anæsthesia could be assigned its proper place it was necessary to know: (1) how long the anæsthetic agents remained in the dural canal, and what effects apart from analgesia they produced there; (2) what immediate or remote effects the drugs employed had on the structures with which they came in contact; and (3) how the drugs injected were eliminated. He himself had investigated only stovaine. He had used a method which would indicate the presence of stovaine in a dilution of 1 in 150,000. He quoted figures to show that the drug could usually be detected within the dura mater for about two days 48 hours after injection the cerebro-spinal fluid was invariably turbid from the presence of leucocytes. In a case examined three days after puncture there was no sign of local inflammation. Although the drug could be detected for 48 hours the average duration of analgesia was only from one to two hours. In the urine no stovaine could be found until the forty-fifth hour. Post-mortem histological examination of the cord gave contradictory results.

HÆMATOLOGY AND VACCINE THERAPY.

WEDNESDAY, JULY 28TH.

President, Sir ALMROTH WRIGHT (London).

The PRESIDENT opened the proceedings with a discourse on

Retrospect and Prospect in Vaccine Therapy.

He expressed his satisfaction at the action of the Association in creating such a section, which had rather surprised him since it was only eight years since he first called attention to the curative properties of vaccines in connexion with staphylococcic infections. He traced the history of vaccination, commencing with Jenner down to Pasteur, who worked chiefly with rabies and prophylactic inoculation against various diseases of animals; Ferron, who initiated anti-cholera vaccination, and Haffkine who continued this work. Up to this time only living microbes were used for the purpose of immunisation, but in the antityphoid vaccination which he himself had initiated, and later in Haffkine's antiplague work, living cultures were definitely discarded in favour of vaccines killed by heat, and at the same time it was only with this antityphoid work that the changes in the blood following inoculation were studied and the dosage scientifically adjusted. Leaving prophylactic inoculation, the President traced the course of therapeutic use of vaccines, beginning with tuberculin, which, used empirically, as it was at first, he described as a jump in the dark, which jump fell far short. He insisted on the great importance of controlling such inoculations by blood tests when experimenting with new vaccines, as without such they were in the same posision as the early users of old tuberculin, who were quite ignorant of the changes they were inducing in the body by their inoculations. It was only by systematic blood tests that the great importance of the negative phase was recognised and the consequent necessity for the use of minute doses of the vaccine. He deplored the lack of enthusiasm in this country as regards medical research, and thought it a pity that whereas sportsmen could be found who would institute an anti-grouse league for the investigation of grouse disease, yet it seemed impossible for a like number of persons afflicted with diseases such as bronchitis, asthma, or the like to form anti-bronchitic or anti-asthmatic clubs for the investigation of that specific complaint.

Mr. L. NOON (London) read a paper on

The Influence of the Site of Inoculation on the Immunity Produced.

He said that there were three alternatives which might be suggested as to the origin of antibodies in response to the inoculation of antigens: (1) they are formed after absorption of the antigen into the circulation and, either in the blood-stream or in some tissue, which cannot yet be defined; (2) they are formed from the tissues at the site of inoculation; (3) they are formed by the leucocytes, either at the site of inoculation or elsewhere. If (1) be accepted then the site of inoculation is only important as it determines a quicker or slower absorption. But, assuming (2) or (3) to be true, the site becomes of great importance because we may be able to increase immunity by stimulating a sound tissue, without adding more poison to that added on by the structures in disease. The experiments quoted show that in normal rabbits inoculated with a vaccine of B. pseudo-tuberculosis rodentium three distinct types of immunising reaction followed respectively the subcutaneous, intravenous, and intraperitoneal inoculations. The reactions were measured by opsonic observations. Subcutaneous inoculation gave a good reaction without a preliminary negative phase, while intraperitoneal inoculation gave a marked and prolonged negative phase which was followed by a raised immunity only in some cases. Intravenous inoculation produced a good immunising reponse, preceded (in the case of large doses) by a well-marked negative phase of short duration. It is probable, therefore, that the subcutaneous tissues offer the safest site for therapeutic inoculation, and that these only become dangerous when the vaccine material is easily absorbed into the circulation. Such absorption can be combated at present by the use of minimal doses carefully controlled by experiment.

Dr. A. BUTLER HARRIS (London) said that when he first started using tuberculin he thought that it did not matter where the inoculation was given, but during the last two years he had found it of advantage to inoculate near the seat of the lesion.

Dr. W. M. CROFTON (Sutton Bridge) also discussed the paper.

Dr. F. L. GOLLA (London) read a paper on

The Anti-tryptic Index.

He referred to the electrical conductivity method of measuring this, which he described in THE LANCET of April 3rd last, and as an alternative method he has adapted the viscosity method of Spriggs, by which the test can be done at room temperature and the result can be obtained in 30 minutes. This simpler method gives almost as good results as the former one. The results show that the anti-tryptic power of normal healthy persons is constant within the limits of error. Patients were tested having varying degrees of fever and various indices were obtained, but there was no correlation between the temperature and the anti-tryptic power. In pulmonary tubercle some were found to have high indices and others were comparatively low, and while those with the low indices progressed on the whole, those with high indices gave the least favourable results with treatment. The effect of the injection of tuberculin on the index was to increase it markedly in those patients who had low indices, while its effect on those showing in the beginning high indices was very slight, if any. Several cases of pulmonary tuberculosis shortly before death all showed great increase in the antitryptic power, whereas some cases of purely surgical tubercle gave normal results. In other diseases there was often a marked increase in the index, and especially was this seen in pneumonia, where this high index was maintained without change for some time after the crisis. In scarlet fever, typhoid fever, [illegible] the index is to be regarded as due to the absorption of the products of cell destruction.

Dr. A. FLEMING (London) said that working with a method described some two years ago by Sir Almroth Wright he had found the index high in pneumonia and in tuberculous cases where there was a secondary infection, but in the patients with tubercle, in which there was no such secondary infection, the index was normal, from which he concluded that the rise in the index had no direct relation to the tuberculous infection; but was due to the secondary invasion with pyogenic bacteria.

Professor SANFELICE (Bologna) read a paper on the

Genesis and Cure of Malignant Tumours.

He divided workers in cancer into three categories: 1. Pure morphologists who did not indulge in experimental methods and who were violently opposed to the parasitic theory and who denied to those who hold to this theory even the intellectual capacity to understand what may be a carcinoma and what may be a sarcoma. 2. Experimentalists who in late years have almost all had a real mania for procuring for themselves a rat or mouse with a spontaneous tumour for initiating a series of transplantations through many generations, as if this method of research could solve the question. This, he considered, marks a retrogression, as most of the observers tend to elevate the neoplastic cell as an etiological agent in itself, returning thus to the ancient conception of Cohnheim. 3. Partisans of the parasitic theory grounded on the pathogenic action of blastomycetes. This consists only of few workers, if we exclude those who by publications based on little work tend to throw discredit on the theory. It is known that a malignant tumour may be transplanted from one animal to another, and if the second animal overcomes the first inoculation an immunity is established. The spontaneous tumours are, however, the secondary effect of a cause hitherto unknown, but from researches initiated in Cagliani in 1894 Professor Sanfelice found that in malignant tumours of men and animals there existed pathogenic saccharomycetes which, however, could only rarely be cultivated as they were transformed into Russel's atoms by the action of an antibody existing in the serum of the infected animal, the change being a fusion of the chromatic substance and resolution of the parasites into small round bodies. These blastomycetes in cultivation are seen to be coagulated exactly like those forms which were considered by Soudakewitch, Prusser, and Plimmer to belong to the protozoa. These blastomycetes inoculated into guinea-pigs and rabbits caused tumours consisting for the most part of parasites (pseudo-tumours), but when inoculated into dogs in smaller numbers they gave rise to true epithelial neoplasms. From his preliminary researches Professor Sanfelice was convinced that the parasites were not transported into the metastases of the tumours, but that these were due to some chemical stimulus, this being of the nature of a toxin elaborated by the blastomycetes in the tumour. He noticed that when he inoculated the parasites alone on to the trachea of a dog they multiplied but there was little cell proliferation. When, however, some of the culture medium was inoculated also there was marked proliferation of the cellular elements. He had obtained a fluid medium in which the blastomycetes produced a very active toxin which; when inoculated into animals, gave rise to malignant tumours similar in structure to those we meet with in man. Professor Sanfelice stated that with the discovery of the toxins we had explained the *genesis of malignant tumours.* The parasite exists in the mucous membranes or skin, and when for some reason or other the resistance of the body becomes diminished these multiply, producing toxin which stimulates the cellular elements to atypical proliferation. When the parasites die they excite an immunising response whereby antibodies are produced which transform the blastomycetes into little fuchsinophile bodies. These toxins when inoculated into dogs evoked the production of antibodies. First the attenuated toxin is introduced subcutaneously, then the integral toxin, and the antitoxins formed were at a maximum in three months. This antiserum is potent, one-tenth cubic centimetre being able to neutralise ten fatal doses of living parasites. The history of the tumour depends on the amount of immunising response; thus when there is a good response there is a slow growth or even retrogression, but when the response is weak then growth is rapid and dissemination early. As regards the treatment with his antiserum, Professor Sanfelice said that in all of 14 dogs affected with various malignant tumours complete recovery ensued in five or six months. If metastases were present these disappeared before the primary tumour. His work up to the present led him to believe that the same results can be obtained in man as he had obtained in animals.

Dr. CULLEN (Baltimore) congratulated Professor Sanfelice on his very important communication, and stated that he had had an opportunity of seeing the specimens of tumours before and after treatment with the curative serum, and they afforded a most conclusive proof of the great efficacy of the serum in malignant disease.

Professor SANFELICE subsequently gave a demonstration of his microscopical specimens in the pathological museum. The specimens shown comprised sections of spontaneous tumours which he had found in animals and also tumours which he had produced artificially by inoculation of animals with the products of his pathogenic blastomycetes. They formed complete series showing the remarkable changes which took place in these tumours as the result of the injection of his curative serum, the specimens having been taken before and at intervals during the course of treatment. Some of the tumours shown appeared to be of a typical carcinomatous nature, while others were sarcomatous in type, but in both the result of the injection of the serum seemed to be chiefly marked by a degeneration of the cells of the neoplasm till in the final stage when cure was complete there remained only a small amount of stroma, apparently absolutely devoid of cancer cells.

Dr. THOMAS HOUSTON (Belfast) read a paper on

Typhoid Carriers.

He referred to a case he had already published of a patient who had symptoms of cystitis accompanied by general ill-health, but who had no history of an acute attack of typhoid fever. His second case was reported in THE LANCET of Jan. 30th, 1909, p. 311. This patient suffered from headache but had no fever. Seven years ago she had typhoid fever, and since then six patients living in the same houses had developed the disease. This patient was cured with typhoid vaccine. The after-history of the patients infected by this case was as follows. The first made a good recovery. The second suffered from headache and malaise for six months but no investigations were made. The third, a nurse, was still infected with typhoid bacilli at the end of six months, but this cleared up with vaccine treatment. The fourth had typhoid bacilli in her fæces after six months and her serum gave a positive Widal's reaction. A dose of 50,000,000 typhoid bacilli raised the temperature for two days, after which it remained normal for three months. The case was then lost sight of. The third case investigated had had an irregular temperature for four months. Typhoid bacilli were found in the urine in large numbers. Her sister, returning from a holiday, developed typhoid fever, and six months afterwards still had typhoid bacilli in her urine. Both cases were treated with typhoid vaccine. The cases described were plasmon. Messrs. Savory and Moore, of 143, New Bond-street, London, W., exhibited a number of foods for infants and invalids, amongst the former being a food designed for use with fresh milk, the digestibility of which it promotes owing to the formation of curdy lumps in the infant's stomach being prevented. This firm also exhibited their well-known peptonised preparations of milk, milk and cocoa, and coffee and milk. Close by Messrs. Callard and Co., of 74, Regent-street, London, W., showed an interesting variety of starchless and sugarless foods and beverages, including jams, cakes, bread, marmalade, jellies, whisky, ginger ale, lemonade, and so forth. Vacca milk attracted considerable interest at the stall of the Vacca Milk Company, Limited, of Amsterdam, Holland, by reason of its excellent taste, fresh state, and quality, and yet it is sterilised but without being boiled. As we have pointed out in our analytical columns, there should be a great future for a process which has solved the problem of sterilising milk without heat and without the use of chemical preservatives. It is not surprising to learn that the milk is giving good results in dietetic practice both in regard to infant and invalid feeding. Amongst pre-digested foods of recognised value it is hardly necessary to mention Carnrick's beef peptonoids in the form of both liquid and powder (Carnrick and Co., 24 and 25, Hart-street, Bloomsbury, London, W.C.), which are necessarily rapid nutrients prepared with the aid of pepsin and pancreatin from beef, wheat, and milk. Special foods adapted for the use of sufferers from diabetes, dyspepsia, and obesity formed the feature of Messrs. G. Van Abbott and Sons' exhibit (Crosby-row, Borough, London, S.E.), which included an excellent series of preparations apropos of food in disease. Next was shown by M. Hoff, of 29, New Bridge-street, London, E.C., a liquid malt preparation possessing a higher nutritive value than stout, but practically without alcohol. Messrs. Keen, Robinson, and Co., Limited (incorporated with J. and J. Colman of London and Norwich), of Denmark-street, St. George's-in-the-East, London, E., had an attractively arranged stall on which were shown specimens of Robinson s "patent" barley and groats, both known for their excellent quality and appetising flavour; besides were samples of Colman's mustard and mustard oil and sinapisms. Digestive ferments and preparations embodying pre-digested meat foods were the decided feature of Messrs. Armour and Co.'s exhibit (Atlantic House, Holborn-viaduct, London, E C.). Thus there were elegant preparations of pepsin and pancreatin, glycerole pepsin and glycerole pancreatin, peptonising tablets and powders, peptones, glycerine extract of red bone marrow, bone marrow perles, suprarenalin preparations, trypsin and glycerole trypsin, lecithin, and a series of glandular extracts in powder and tablet form. There were several preparations of interest also on the stall of Messrs. Fairchild Bros. and Foster (London, E.C.), notably "pepules" containing digestive agents; panopeptin, a digested beef and wheat flour product of obviously rapid nutritive power; pepsencia, an aid to the gastric function, and specimens of lecithin. The entirely starch-free and soluble food of Messrs. Mellin (Peckham, London, S.E.), which when mixed with milk gives a food approximating to the composition of human milk, and, besides, is found to be digestible and nutritive, particularly for infants and for those prone to gastric disturbance, was the chief exhibit of this firm, but there were shown also some good biscuits and chocolate, and as accessories a graduated feeding-bottle and a "baby balance." "Virol" (Virol, Limited, 152–166, Old-street, London, E C.) is now firmly established as a valuable food in wasting diseases, which, having regard to its composition, is not surprising. It consists of bone marrow, red bone marrow, malt extract, eggs, and lemon syrup. Messrs. Bovril, of the same address, exhibited many specimens illustrating the applicability of bovril in a number of preparations to useful dietetics. Another well-known food product shown was Horlick's malted milk (Malted Milk, Limited, Slough, Bucks), a full-cream preparation modified by active malt extract, so that the digestibility of the milk protein is increased. Mr. A. Wander, of 1 and 3, Leonard-street, City-road, London, E.C., exhibited samples of ovaltine, which, as our own analyses have shown, contains all classes of reparative materials and includes also lecithin, the organic phosphorus compound, amongst other things, in egg and the milt of male fishes. The exhibit included an active dry extract of malt and formitrol, a pastille developing formaldehyde for the antiseptic treatment of the mouth and throat. Messrs. Brand's stall (11, Little Stanhope-street, Mayfair, London, W.) offered a remarkable variety of invalid foods, including the essences of beef, mutton, veal, and chicken, while there were also various meat jellies which have a reputation as attractive and nutritious preparations in the invalid's dietary. Cocoa was worthily represented by Messrs. Cadbury, Brothers, Limited, of Bourneville, near Birmingham, who drew the attention of the visitor to the care taken to maintain strict hygienic conditions at their works. A life-sized model of one of the prize Hereford bulls kept on their estancias in the Uruguay and Argentine Republic served successfully to attract visitors to the exhibit of the Liebig's Extract of Meat Company (4, Lloyd's-avenue, London, E.C.), whose representative, Mr. Mason, explained the merits of the beef preparations shown, especially in regard to their use for invalids. A point in considerable favour of the Liebig's Company's animal food products is that they are obtained under a system of medical and scientific control which precludes their contamination by disease.

(To be concluded.)

BRITISH MEDICAL BENEVOLENT FUND.

AT the July meeting of the above Fund 22 cases were considered and grants amounting to £195 voted to 19 of the applicants, three cases being passed over. Four annuitants were elected to fill vacancies caused by deaths. Appended is an abstract of the cases relieved by grants:—

Daughter, aged 70 years, of late M.R.C.S. No income; has been supported for several years past by a brother who is now compelled to withdraw his help. Relieved once, £10. Voted £18.

M.B., C.M. Glasg., aged 56 years. Is not in very good health and finds difficulty in obtaining suitable work. No children. Voted £5.

Daughter, aged 73 years, of late M.R.C.S., who practised as an army surgeon. Lost everything through the dishonesty of the family solicitor (since struck off the Rolls) and has exhausted a small legacy received a few years ago. Voted £18.

Widow, aged 58 years, of M.R.C.S., L.S.A. Supports herself by letting lodgings, but is in arrears with rent owing to last year's bad season, and is now threatened with loss of her furniture. Voted £16.

Widow, aged 71 years, of M.R.C.S. Only income the Old Age Pension of 5s. a week, and is crippled by rheumatism and sciatica. Voted £12.

Widow, aged 43 years, of M.R.C.S., L R.C.P. Quite unprovided for at husband's death in January last and dependent on relations who can ill afford to help. Two children, aged nine and seven, both candidates for institutions. Voted £10.

Daughter, aged 58 years, of late L.S.A. No income; lets lodgings, but finds the profits insufficient for her support. Relieved once, £12. Voted £12.

Widow, aged 52 years, of L.R.C.P. No income; is in ill-health and unable to follow any active employment. Only child barely self-supporting. Relieved twice, £24. Voted £12.

Widow, aged 40 years, of L.R.C.P. Edin. Supplements a small income by district nursing, but has incurred unusually heavy expenses through the illness of one of her children. Relieved twice, £10. Voted £5.

Widow, aged 63 years, of L.R.C.P. Edin. Has an annuity of £20 and earns a few shillings a week by addressing envelopes and by needlework. Two sons, but neither able to help. Relieved 12 times, £126. Voted £5.

Daughter, aged 28 years, of late M.D. Dub. Has never had good health, and at present is quite unable to follow any employment and dependent on mother whose income is less than £1 a week. Relieved four times, £25. Voted £5.

Widow, aged 48 years, of L.R.C.S. Edin. Income £16 a year, and receives assistance from her mother. Children unable to help. Relieved five times, £50. Voted £5.

Widow, aged 40 years, of M.R.C.S., L.R.C.P. Has supported herself as a working housekeeper, but is losing her post through the breaking up of the home. Two children, aged 18 and 14 years, the younger in bad health following influenza. Relieved five times, £35. Voted £10.

Widow, aged 48 years, of L.R.C.P., L.R.C.S. Edin. No income and children only able to give very slight help. Relieved 13 times, £141. Voted £5.

M.D. Lond., aged 67 years. Is quite incapacitated by hemiplegia and dependent on friends who can ill afford to help. Relieved once, £18. Voted £18.

L S.A., aged 63 years. Only income an Epsom College pension and suffers from a nervous complaint which quite prevents practice. Children unable to help and wife dying from new growth. Relieved three times, £54. Voted £10.

Daughter, aged 63 years, of late M.D. Only income a few shillings a week, and has been obliged to give up post as companion on account of ill-health. Relieved twice, £24. Voted £12.

Widow, aged 73 years, of M.D. Glasg. Lets lodgings but has had one set of rooms vacant for six months. Children unable to help. Relieved six times, £31. Voted £5

Daughter, aged 63 years, of late L.S.A. Only income a small annuity and has to support an invalid sister who is entirely without means. Relieved 11 times, £103. Voted £12.

Subscriptions may be sent to Dr. S. West, treasurer, 15, Wimpole-street, London, W.

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1909.

The British Medical Association: The Address in Obstetric Medicine.

THE unique facilities afforded in Ireland for the clinical study of obstetric medicine have enabled the Irish school of obstetricians to attain a position of acknowledged eminence in this branch of medicine. It was therefore most fitting that one of that school should be selected to give the Address in Obstetrics at the meeting of the British Medical Association at Belfast. In his most interesting address (which is printed in another part of our present issue) Sir JOHN BYERS surveyed the modern position of obstetric medicine and surgery, and suggested the lines of advance along which progress may be expected in the future.

A quarter of a century ago, on the occasion of the first meeting of the British Medical Association in the north of Ireland, the late Dr. GEORGE KIDD delivered an Address in Obstetrics, selecting for his subject puerperal fever, even now the most important question in this field of practice. At that date (1884) the belief in the epidemic occurrence of child-bed fever still prevailed, and Dr. KIDD came to the conclusion that there were a large number of cases which came within such a definition, and that the epidemic thus constituted was a specific disease. During the quarter of a century which has elapsed since that time our knowledge of the causation of puerperal infection, as we prefer to call it at the present day, has become much more exact; we know that it differs in no way from surgical septicæmia, and we have a very accurate knowledge of the numerous organisms which play a part in its causation. Indeed, in lying-in hospitals the prevention of the disease has reached such a pitch of perfection that it may be considered to have been banished from all such institutions, at any rate in its severer forms, with the rarest possible exceptions. No longer do we reckon the success of these institutions by their mortality rate, but rather by their morbidity rate. It is a great pity, as Sir JOHN BYERS points out, that the various maternity hospitals are not agreed as to the physical indications of puerperal septic morbidity. It would be of the greatest value in the compilation of statistics if some general agreement on this matter could be come to. At the present time almost every hospital has a standard of its own, with the result that there is a good deal of confusion. We could wish that they would all adopt some such standard as that recommended by the Committee on Puerperal Morbidity appointed by the British Medical Association, since the actual standard determined upon is not of so much importance as uniformity in the matter. The extreme importance of the morbidity of child-bed is well known to all gynæcologists; indeed, it may truthfully be affirmed that the gradual diminution in the number of such cases, which we may hope the future will bring, will result in a great lessening of the cases of chronic pelvic inflammation which at the present time are so common amongst gynæcological patients. That such a diminution is even now occurring and at a progressive rate Sir JOHN BYERS demonstrates by quoting the statistics of the Rotunda Hospital, where the percentage of morbidity has shown a steady decrease during the last few years. And this improvement is seen also in the results of the practice of the Belfast Maternity Hospital, and, indeed, in all the lying-in hospitals of the country. It has been brought about by the recognition of the fact that labour is a natural process, in the great majority of cases not needing any interference, by the thorough application of the most minute surgical cleanliness, and by the observance of CREDÉ'S teaching that even the simplest internal manipulation in a lying-in woman may cause septic infection. At the present time, when so much is being made of the necessity for instructing students in the methods of external examination, it is interesting to read the quotation given by Sir JOHN BYERS from CREDÉ'S views enunciated as far back as 1886, where he says, "To instruct their pupils as thoroughly as possible in this method of external examination is the present and future duty of teaching institutions." It has been objected that cases of puerperal septic infection occasionally arise even when the patient has never been examined internally at all, and such instances have been cited as examples of auto-infection. It is impossible to say that cases of auto-infection never occur, but as a rule in these cases a source of the infection will be found either in some other part of the patient's body or in her environment. In the etiology of the great majority of the cases of puerperal infection we may consider it certain that auto-infection plays no part, and it is our duty to rigidly exclude all possibility of failure in regard to our observance of surgical cleanliness before comforting ourselves with the conclusion that the patient has infected herself. At the present time there is a small but steady decline going on in the death-rate from puerperal infection in England and Wales, and we may hope that this is the result of the greatly improved teaching which students and nurses undoubtedly are now receiving. The death-rate is still one of appalling magnitude when we consider the results obtained in lying-in hospitals, but that there is hope for the future may be gained from a perusal of the figures which Sir JOHN BYERS quotes.

In his survey of the improvements which can be recognised in the field of operative midwifery Sir JOHN BYERS calls attention to the increasing tendency to avoid craniotomy if possible on the living child. It is not practicable at present, nor indeed do we think that it ever will be, to exclude craniotomy entirely from the field of operative midwifery, but with a better knowledge of the course of labour in cases of contracted pelves and with the more general performance of Cæsarean section we may hope for a further decrease in the number of these horrible operations. The results obtained of recent years in maternity hospitals in the treatment of cases of contracted pelves have served to demonstrate in a most striking fashion that a very large percentage of such cases will terminate spontaneously without interference. Indeed, in Professor SCHAUTA'S clinic at Vienna in no less than 80 per cent. of the cases of contracted pelves labour occurs spontaneously at full term. Not only does labour terminate in these cases without artificial aid, but the results surpass those obtained by any other mode of treatment than Cæsarean section. Sir JOHN BYERS shares the dislike which is felt by so many German and American obstetricians to the induction of premature labour in the treatment of contracted pelves. The gradually increasing opposition to this operation is most curious and is opposed to the opinion held as to its merits by the London school, who practise it extensively with very good results, both to the mothers and the children. The recommendation given for the performance of pubiotomy in cases where the child is alive and uninjured will not find much endorsement among English obstetricians, for this operation appears to have made but little headway in this country.

In considering the future development of obstetrics the speaker referred to the more thorough practical training of students and pupil midwives, the public health aspect of obstetric medicine, and the more intimate association in the future of the physiological chemist and the pathologist with the practical obstetrician. The movement for the more practical training of students, initiated by a committee appointed by the Royal College of Physicians of London and also by the General Medical Council, has made considerable progress; and at the present time examining bodies, following the lead given them by the University of Cambridge, are beginning to move in the matter. The University of Belfast has adopted the recommendations of the General Medical Council, and has decided to hold a clinical examination in midwifery and gynæcology. But we fear that the suggestions put forward by Sir JOHN BYERS as to raising the standard of general education among midwives and his proposal to increase the duration of their training to six months or even to one year are quite impracticable. That a midwife should have had a surgical and medical training if possible we quite agree, but in view of the great difficulty which exists in obtaining the necessary number of women to take up this profession any attempt to increase the expense attendant upon the training is bound to meet with failure.

Among the urgent necessities of the future are an increased knowledge of the many problems connected with ante-natal pathology and an increased knowledge of the best means for combating these conditions. The modern obstetrician, as Sir JOHN BYERS truly says, has two duties constantly impressed upon him: he must look after the interests of the mother, not merely in her hour of trial at childbirth, but also before and after that event, and he must also have a thorough acquaintance with the best means of preserving the life and promoting the growth and welfare of the newborn infant. If the ideal of a healthy mother and a healthy child is to be realised, then more and more among the people must be spread the knowledge of motherhood. Much of the heavy infant mortality which to-day prevails in all our large cities is due to the entire absence among the mothers of the *poor of even the most elementary knowledge of* what is required for the proper rearing of healthy children. The problem of better training for the medical man and the nurse is an important one, but not one whit less important is the training of the mothers themselves, so that the advantages of the skilled advice given by the trained practitioner and nurse may not be entirely thrown away. Much has been done in this direction of late years, but much remains to be accomplished. The large amount of assistance which the physician of the present age derives from the worker in the pathological laboratory is one of the most striking features of modern medicine. Who can doubt but that many of the problems in connexion with such a disease, for example, as eclampsia, will be solved ultimately by the joint coöperation of the clinician and the research worker in the laboratory? To attempt to practise scientific medicine without the assistance of the physiological chemist or of the clinical pathologist is an impossibility, and if the science of obstetric medicine is to advance in the future so as to enable us to solve the many problems which still confront us it must be by the cordial and combined efforts of all these workers.

◆

Mortality Statistics and Public Health.

FAMILIARITY with the history of sanitary progress in England during the last quarter of a century makes it impossible to doubt the beneficial effect which the publication of mortality statistics has exercised on public health administration throughout the country. It would, indeed, be difficult to over-rate the influence on public health of the 70 annual reports issued since 1837 by successive Registrar-Generals, with the help of their medical advisers, Dr. FARR, Dr. OGLE, and Dr. TATHAM. The present time, when the General Register Office is passing under the control of a new Registrar-General and a new Medical Superintendent of Statistics, seems opportune for seriously considering whether, in the interests of the public health, the value of these annual reports could not be further increased and their influence on sanitary progress strengthened.

Medical officers of health and those of the public who are interested in mortality statistics can scarcely fail to regret that the main statistical units in the Registrar-General's annual reports still continue to be the registration districts, and the aggregations of those districts, called registration counties, instead of sanitary districts and administrative counties as they should be. This defect is due to the fact that the system for the registration of births and deaths was, by the Act of 1836, based upon the Poor-law organisation, because at that time no systematic sanitary organisation existed. The value of the Registration Act, as a basis for vital statistics and for promoting public health, was, indeed, scarcely recognised by its promoters, and even the provision of a column in the Death Register for recording the cause of death was an afterthought. The Act provided that each Poor-law union should be divided into registration sub-districts and that a registrar of births and deaths should be appointed for each sub-district. Since 1837 every change in the boundary of a Poor-law *union has necessitated a* corresponding change in the registration district, and frequently also in the registration county. Thus in the earlier annual reports of the Registrar-General the vital statistics necessarily dealt almost exclusively with Poor-law areas. Since the creation of sanitary districts and of administrative counties, which are but seldom co-extensive with registration districts and registration counties, a desire has naturally arisen for official statistics relating to administrative areas. It cannot be denied that the omission of such statistics detracts from the practical value of these annual reports, since the local influence of official mortality statistics for the promotion of public health is inappreciable unless the statistics relate to the exact boundaries of the several administrative areas. It is, moreover, impossible to overlook the importance of authoritative statistics for administrative areas to the Medical Department of the Local Government Board, which department, it may be hoped, will one day form part of an independent ministry of public health. It is true that the weekly and quarterly returns of the Registrar-General, and his annual summary, contain valuable, although somewhat rudimentary, statistics relating to 76 of the largest English towns, directly derived from returns furnished by the local registrars of those towns. The annual reports, however, contain no particulars of ages and causes of death in sanitary administrative areas (except in London), although these statistics would be infinitely more useful than the statistics now prepared for registration districts and counties in which no one is really interested. This defect applies equally to the decennial supplements to the annual reports, the value of which would undoubtedly be increased by the substitution of tables relating to sanitary areas and administrative counties for those relating to registration districts and counties, which in Dr. TATHAM'S last Decennial Supplement, for the years 1891-1900, occupied more than 700 pages. The sex, ages, and causes of death have been invariably classified at the General Register Office for each registration district separately. But the best interests of sanitary progress would seem to require that future reports of the Registrar-General should contain additional mortality tables relating to a certain number of the larger towns, which tables might be somewhat similar in character to those relating to registration districts in the last Decennial Supplement.

We are informed that in certain instances the registration districts are already co-extensive with urban sanitary districts, and that the separate classification of small numbers of deaths in cases where portions of a sanitary area are situated in two registration districts would not involve serious additional labour, whilst it would add materially to the utility of the results. If tabulated statistics relating to all towns that are now co-extensive with one or more registration areas were at once added to the annual reports, the separate classification of parts of registration areas that would render statistics available for other towns could be added from time to time. In anticipation of probably far-reaching changes in Poor-law organisation in the near future, which may facilitate the substitution of sanitary districts for the present registration districts, it seems not only desirable but quite practicable, to increase the value of the Registrar-General's annual reports by the preparation and publication of statistics for administrative counties, and for so many of the larger sanitary districts as may from time to time be found desirable.

"Secret" Remedies.

WE published recently[1] a valuable letter from Mr. G. P. FORRESTER upon the restriction of unqualified practice and the sale of secret remedies in Germany. This week a somewhat similar letter has reached us from a correspondent in Sweden, and the two communications may well serve both to call attention to the character of the traffic in "secret" remedies as it is carried on in Germany and in Sweden, and also to the efforts which are being made in those countries, either by public authorities or by professional bodies, to diminish the evils which this traffic brings in its train. The tendency to purchase quack medicines, and to believe in the representations of quacks, has existed from time immemorial, and was satirised by GOLDSMITH, 150 years ago, in terms which would require little alteration in order to render them equally applicable to the conditions of the present day, were it not for the increased facilities for advertising which have been created by modern conditions, and for the somewhat increased deference now paid to financial prosperity, without reference to the manner in which it has been attained. GOLDSMITH'S Chinese philosopher regarded it as marvellous that, although there was no disease which was not curable by a specific which could be bought for half-a-crown, there were still people who thought it proper to be ill or even to die; and he also wondered that so many of the most highly gifted of the quacks of the time had remained unconscious of their powers of healing until a bankruptcy or a residence in jail had called those powers into exertion. In the present day the "proprietors" of quack medicines drive about in carriages, are permitted to mix with decent people, and endow charities when they die; but the essential nature of the creature remains unchanged. He is still a useless and dangerous parasite upon the body politic; he robs the sick poor of sums of money which in the aggregate are enormous and which in detail are often obtained for him only at the cost of much privation; his preparations, composed of the most familiar drugs and sold at 50 times their value, are often (as in the case of many drastic purgatives) absolutely injurious to those who make a practice of swallowing them; and are still more often negatively injurious by interfering with proper treatment. A familiar example of this is furnished by the preparations which, under various names, are sold for the cure of "blotches" and other affections of the skin, and which generally owe a totally deceptive efficacy to iodide of potassium. They frequently do apparently "cure" the condition for which they are administered; and they leave the "cured" person to infect wife and children with syphilis, or possibly to die himself from some of its tertiary forms. Another difference between GOLDSMITH'S quack and our own is that the former was often ignorant of the mischief he was likely to be instrumental in effecting; while in the present day the putting up of a "secret" remedy in a permanent and attractive form requires the possession of at least some small amount of pharmaceutical knowledge, knowledge which must be sufficient in most cases, and especially in those of the many alcoholic and narcotic "remedies" now placed upon the market, to render him fully cognisant of the grievous injury to individuals and to the community which the consumption of his preparations is likely to produce.

---

[1] THE LANCET, July 17th, p. 183.

Our correspondent who deals with the question as it presents itself in Germany tells us that in the financial year 1898–99 a sum of one million and a half sterling was spent there on secret remedies; and we have seen an estimate, based upon the returns of the Stamp Office, showing that about double this amount is annually spent in the same way in the United Kingdom. It is not quite clear what population the word "Germany" embraces, but it must in any case be a larger one than our own, and hence the various restrictive measures described in the letter must have at least some effect in reducing the dimensions of the evil. What these dimensions are among ourselves we shall probably hear before long as a result of the inquiry which, at the instance of the General Medical Council, the President of the Local Government Board has decided to institute through the medium of medical officers of health; and we may reasonably hope that it will then become possible to follow to some extent the example which has been set in Sweden, and to obtain combined action from the legislature and from the professions and callings interested, for the purpose of diminishing an evil which everyone must admit to be serious. The credulity by which quackery and quack medicines are supported is primarily, of course, a result permitted by defective education; often not defective as far as the "humanities" are concerned, but defective, or even non-existent, with regard to the laws of life and health, laws of which it is not uncommon for our legislators to display the most supreme and ghastly ignorance. We think it probable that no small amount of light would be thrown upon the subject if the coöperation of the Board of Education could be obtained in the conduct of the projected inquiry, and if the medical officers appointed to conduct the medical inspection of school children could be instructed to ascertain, as far as might be possible without impertinence, the nature of the prevailing mental attitude of the teachers of elementary schools towards quack medicines, and their habits with regard to the practice of buying or swallowing them. We should not be in the least surprised if it were found that teachers, as a rule, share the popular view that a disease is a definite entity, like, as Miss NIGHTINGALE said, "a cat or a dog," and that a "remedy," calculated to expel it from the system, can be purchased in a bottle and successfully applied without examination of the actual state of the sufferer. This belief is, in fact, the foundation upon which the whole iniquitous system of "secret" remedies is built up; and the growing influence of the healing profession upon the teaching profession can be exerted in no better way than in assisting to dispel it. The practice described as prevailing in Sweden, of making public the composition of "secret" remedies, and of showing the ordinary worthlessness of their ingredients, is one which might probably be adopted in this country with excellent eventual results.

A very serious question in relation to all forms of quackery is the great and increasing assistance furnished to them by the newspaper press, and also, it may be said, by the printing trade in general, a trade of which quacks are munificent patrons. According to our correspondent, the Swedish press is fully aware of the nefarious uses to which its advertising columns are applied, and professes absolute inability to interfere by any attempt to exclude fraudulent advertisements. We have heard much the same thing said in this country, and we remember that it formed the staple excuse of the incriminated papers for the harvest which they were deriving from the scarcely-veiled advertisements of abortionists at the time when we called attention to the facilities offered by the press for the commission of grave crime. The excuse seemed and seems to us a wholly insufficent one. The conductors of newspapers are perfectly well aware that, in the existing stage of public education, thousands of people have learned to read who are absolutely incapable of exercising any sound judgment about the printed matter which is placed before their eyes, and who really draw no distinction between what "the paper" says about somebody's pills and what it says about the movements of Royalty, or about the Budget, or the unemployed. The power of the press is greatly in excess of the knowledge of large numbers of those to whom its columns are addressed, and we cannot admit the complete freedom from responsibility for advertisements which is frequently claimed on its behalf. Moreover, many of the statements commonly put forth by quacks are so preposterous in their own nature that the credulity of ordinary ignorance would require reinforcement by the supposed authority of the "paper" before any belief in them leading to expenditure could be rendered even possible. An enormous step would be gained if the proprietors of patent medicines were compelled to disclose their composition. It would then be open to professional associations to make widely known the nature, the properties, and the intrinsic value of every such compound, and to show that the claims put forward on its behalf had no justification. Such exposure, in the case of the quack medicines containing appreciable quantities of alcohol, morphia, or cocaine, might open the eyes of the public to the dangers incidental to swallowing them, and it would also afford to purchasers the protection of the ordinary law which secures that goods sold shall be of the nature and kind demanded by the buyer and specified by the seller.

Annotations.

"Ne quid nimis."

THE EXTINCTION OF YELLOW FEVER AT RIO DE JANEIRO.

FOR many years Rio de Janeiro has had an unhealthy reputation, more particularly as regards yellow fever. In some degree this bad name was due to the fact that a very large proportion of the deaths from this disease occurred among the newly arrived foreigners or immigrants, no less than 83 per cent. of the yellow fever deaths, increasing to 90 per cent. in epidemic years, being referred to them. With varying conditions the number of deaths fluctuated from year to year. In the 13 years period ended December, 1902, the yellow fever deaths amounted to 22,506, or an annual average of 1731, and during that time the disease was regarded as highly infectious. Much attention was therefore devoted to thorough disinfection of clothing, bedding, and other effects of the sick, but with little result. Some time back the Brazilian authorities had their sanitary conscience awakened, and thereafter strove to find means for reducing the deaths from yellow fever in Rio de Janeiro. To this end a reward of 500,000 francs was offered to anyone who would invent or discover a specific remedy for the disease. Later the success of the American methods in Cuba stirred the authorities in Brazil to action, and it was resolved to carry out in Rio de Janeiro new measures the object of which would be to destroy mosquitoes and prevent their multiplication; to isolate every case, or suspected case, of yellow fever in hospital, so as to prevent any infection of the stegomyia fasciata, the recognised transmitter of the malady; and, lastly, to protect as far as possible susceptible persons from the bites of that species of mosquito. About the middle of 1903 the new measures were begun. A description of the anti-mosquito campaign, as carried out in Rio de Janeiro from 1903 to the present time, is given in a brochure recently published by La Mission Brésilienne d'Expansion Economique, from the pen of M. Nerêu Rangel Pestana, and entitled, "Comment on Assainit un Pays," the subsidiary title being "L'Extinction de la Fièvre Jaune à Rio de Janeiro." This brochure begins by briefly sketching the past history of yellow fever in Rio de Janeiro since 1849, and showing how it became necessary to remove from Brazil's capital the evil name which it had acquired. Acting on the motto that prevention is better than cure, and being profoundly impressed by the results obtained against yellow fever in Havana, the government passed a law making the notification of the disease compulsory under heavy penalty. Protection of the sick by isolation against the bites of stegomyiæ in specially prepared hospital wards was then enforced and war was waged against mosquitoes For this purpose the city, which has now a population of over 800,000, was divided up into sections in which house-to-house visits were undertaken by a staff of 72 medical men assisted by some senior students; the sick were examined where necessary, the sanitary condition of each house was investigated, and advice given for its improvement. A "mosquito brigade" of 1500 men was formed to seek out the breeding-places of the mosquitoes and to remove any conditions likely to favour the multiplication of these insects. All premises were visited once in six days, receptacles liable to harbour larvæ were carted away, cisterns were screened, pools and puddles were treated with petroleum, houses in which yellow fever had occurred or which were infested by mosquitoes were fumigated to destroy these insects. At the same time great attention was given to the general sanitation of the city. New, wide, and open streets were run through the most congested quarters; embankments were constructed along the foreshores; and to some extent a new city arose on the débris of the old one. As already said, these measures were begun about the middle of 1903, and in that year 584 deaths from yellow fever were recorded. Most of them, however, occurred in the hot season, the first three months of the year, before the new measures had come into operation. In 1904, during which 19,914 immigrants arrived at Rio de Janeiro, the deaths from yellow fever numbered only 48. In 1905, when 23,017 immigrants arrived, the deaths from this disease rose to 283, and of these 251, or 88·7 per cent., were foreigners, most of whom on arrival had found shelter in the worst quarters of the city. Some of the cases, indeed, had not been diagnosed as yellow fever at all and had not been protected in the early stage of the malady from the bites of stegomyiæ, so that it is not surprising that fresh crops of cases developed. In 1906 the efforts were redoubled, and although 27,147 immigrants arrived to swell the susceptible portion of the population, there were only 42 yellow fever deaths certified, 35 of them being foreigners. In this year, 1906, as showing the extent of the anti-mosquito measures carried out, it may be mentioned that 153,670 "foyers" of mosquito larvæ were destroyed, 2546 cartloads of old boots and disused cans capable of holding water were removed from the vicinity of houses, 97,461 litres of petroleum and 26,858 of creolin, 1242 kilogrammes of pyrethrum, and 28,603 of sulphur were used in the work. In 1907 there were only 39 yellow fever deaths, notwithstanding that 31,156 immigrants arrived. During 1908 only four deaths from this cause were reported, although no fewer than 46,216 immigrants reached Rio de Janeiro, and in spite of the fact that the season was a very hot one. In the first quarter of 1909, these three months forming the yellow fever season, not a single death was ascribed to this disease. Notwithstanding this "extinction" of yellow fever at Rio de Janeiro, the sanitary authorities of the city continue to persevere in their efforts. From its geographical position the town is very liable to have the disease imported by shipping from the north or from the south, where areas exist in which yellow fever is constantly appearing. If the efforts were abated it is more than probable that the malady would regain its footing in the lower quarters of the city, and again become epidemic as soon as favourable conditions presented themselves. The annual cost of these special measures is estimated at about 3,000,000 francs; but the beneficial results of this expenditure are not limited to yellow fever alone, for since the institution of the measures there has been considerable improvement in the public health with diminution of the general death-rate. Apart from mosquito work, the weekly house-to-house inspections have brought about much improvement in the sanitary condition of premises in the lower parts of the town, and have done much to educate the most ignorant portion of the population in the elements of domestic hygiene.

THE TRAFFIC IN OLD HORSES.

WE have upon many occasions inveighed against the traffic in old and decrepit horses, which, to the discredit of this country, is carried on from London and sundry ports on the North Sea. The wretched animals are shipped to Dutch and Belgian ports, there to be converted into food for the poorer classes of those countries and possibly for other classes in this country as well, for we do not know the ingredients of all the "delicatessen" on the market. We are glad, therefore, to see that in both Houses of Parliament on the night of July 29th the Government answered questions asked by the Earl of Mayo and Mr. Starkey respectively in a sense very favourable to those who have striven against this shocking traffic. Earl Carrington said that the services of a veterinary inspector had been acquired whose whole time would be devoted to enforcing an Order of the Board of Agriculture and to supervising the work of local authorities. The Board of Agriculture was in earnest, and he was confident that the desired results would be secured. If they were not, Parliament would be asked for further powers. Mr. Gladstone spoke to the same effect in the House of Commons. The traffic is one for which no sort of excuse can be found. What is really needed, it seems to us, is an Order prohibiting the exportation of living worn-out horses though administrative difficulty would be connected with such an enactment. The London magistrates have, by a system of heavy fines and occasional imprisonment, almost stamped out the traffic from the London docks, and if similar action were taken by other magistrates and local authorities in ports such as Hull and Newcastle, similar good results might accrue. Apart from the cruelty of the traffic, it is open to question whether we are justified in aiding the Dutch and the Belgians to sell meat from diseased animals to their fellow countrymen. We shall watch for results of the new regulations with interest, and we earnestly hope that in any future prosecutions the magistrate will fine not only the person who may have been leading the horse, but the responsible seller thereof, and that, too, in the largest sum allowed by law, for the best way to impress the people engaged in this odious traffic is to make it plain that it is not profitable.

DEATH FROM MERCURIAL INJECTIONS.

AT a meeting of the Société des Hôpitaux of Paris on June 18th Professor Gaucher again drew attention to the danger of injections of insoluble preparations of mercury in the treatment of syphilis and reported another fatal case of gangrenous stomatitis, which was due to injections of "grey oil," a preparation of metallic mercury much used in France. This is the tenth case of gangrenous stomatitis so produced which has come under his observation in the last few years. Eight of the cases were fatal, and of the surviving patients one has lost part of his maxilla and the other has not recovered at the end of a year. In addition Professor Gaucher has seen a large number of cases of severe but not gangrenous stomatitis due to the same cause, and knows of other cases which have not been published. Several other cases have been reported in the last few years by French writers and some have been noticed in THE LANCET. In the case now reported the patient was a man, aged 71 years, who was sent to hospital by his medical attendant on Sept. 7th, 1908. In 1905 he contracted a digital chancre, and a papulo-squamous eruption rapidly followed and then double iritis for which he was treated at the Hotel-Dieu. In 1906 gummata appeared on the left arm and rapidly disappeared under injections of grey oil. Encouraged by the good effects of the treatment his medical attendant continued the injections, giving a series of five every six months. During two years the only new symptom was an extensive intestinal hæmorrhage. In July, 1908, deafness and facial paralysis appeared and four more injections were given. Then the patient was confided to another practitioner who gave four injections of cacodylate of mercury. At the beginning of August stomatitis commenced. At first it was slight but the inflammation soon increased in extent and depth. On admission there were abundant salivation and horrible fœtor of the breath. Deglutition was difficult and painful. The left half of the soft palate and tonsil were red and swollen, and covered with a greyish exudation. At the angle of the jaw there were adenitis and periadenitis. The urine did not contain albumin. Examination of the buttocks, even with the aid of radiography, did not reveal any nodules left by the injections. Improvement took place; the exudation disappeared and the inflammation became more circumscribed, leaving only a limited gangrenous area on the left anterior pillar of the fauces and tonsil. But the general condition remained serious, and on Oct. 17th a fulminating hæmorrhage took place from the mouth and the patient died in a few minutes. The necropsy showed that the pharynx and tongue were more involved than had been supposed during life; the epiglottis was superficially affected. The source of the hæmorrhage was an ulcerated artery in the tonsil. The kidneys were congested, their capsules were adherent, and microscopic examination showed interstitial nephritis with necrosis of tubal epithelium. Professor Gaucher condemned the use of injections of grey oil as dangerous, and insisted that they were in no way more efficacious than the administration of mercury by the mouth, by which ordinary cases of syphilis could be perfectly treated. In this country Sir Jonathan Hutchinson has given utterance to similar teaching. He finds the use of mercury in the form of pills so convenient and efficacious that he cannot conceive circumstances which should induce practitioners to take the risks which injections involve. If salivation be caused when mercury is given by the mouth the drug can be stopped and ill consequences usually prevented. But when a supply of mercury has been injected only excision of the part can prevent its continuous absorption. In a case recorded by M. Sicard this was done. At the site of injections in the left buttock was a large swelling which radiography showed contained mercury. The swelling was excised and the patient recovered. But the cases in which this operation is possible are exceptional.

WHITE RICE AS A CAUSATIVE AGENT OF BERI-BERI.

IN THE LANCET of Feb. 13th of this year we published a very interesting preliminary communication, entitled "An Inquiry Concerning the Etiology of Beri-beri," by Dr. Henry Fraser, director of the Federated Malay States Medical Research Institute, and Dr. A. T. Stanton, the bacteriologist of that institution. In that paper an account was given of some carefully planned observations undertaken primarily to determine if, when other factors were excluded or controlled, people fed on "white" rice developed beri-beri; and if, on the other hand, among people under exactly similar conditions, except that "parboiled" rice was eaten, beri-beri did not arise. The full details of these investigations have now been published in No. 10 of the Studies from the Institute of Medical Research, Federated Malay States. From an introductory note we learn that Dr. W. L Braddon, lately State surgeon of Negri Sembilan and a well-known authority on beri-beri, was associated with Dr. Fraser and Dr. Stanton throughout the course of their inquiry. It was, indeed, mainly to test the accuracy of Dr. Braddon's views as to rice being the causative agent of this disease that the investigations were carried out. Dr. Braddon, as perhaps our readers are aware, has for some time been drawing attention to the fact that beri-beri is extremely prevalent in the Malay States among the Chinese population who consume white or "uncured" rice as their staple article of diet; while among the Tamils, who use rice prepared by parboiling, and among the Malays living under primitive conditions, whose chief article of diet is rice prepared from "padi" newly husked, the disease is seldom seen. We do not propose to repeat here the details of the tests which Dr. Fraser and Dr. Stanton applied in the course of their inquiry. They were set out in the preliminary communication published in THE LANCET of Feb. 13th, and commented upon by us in our issues of Feb. 20th and May 8th. We wish, however, to refer briefly to some of the conclusions given in the detailed report now published. Shortly, the experiment, if such it may be termed, showed that out of a party of 220 persons in good health fed on white rice, which they preferred to any other sort, 20 cases of beri-beri developed in the period during which the observations were continued, while out of 273 other healthy persons living under identical conditions, except that they were fed on parboiled rice, no sign of the disease appeared. In addition to the 20 beri-beri cases in the first party, it has to be mentioned that there were other instances of illness also diagnosed as beri-beri but which were not included in the list as the clinical characters of the sickness were not typical. None of these atypical cases, however, occurred among the second party. It was not until white rice had been consumed during a period of 87 days that the first symptoms of beri-beri were observed. It was definitely concluded that the malady was not communicable, and that the evidence was against the suggestion that it could possibly be a "place" disease. The substitution of parboiled rice for the white variety at once caused a cessation of fresh attacks among the party in which the disease had been appearing. It may be observed that although rice was the main article of diet, both parties in addition received daily allowances of dried salt fish, onions, potatoes, cocoanut oil, cocoanut, tea, and salt. Based on analyses, the diet issued to those consuming white rice was calculated to consist of proteids, 91·451 grammes; fats, 43·708 grammes; carbohydrates, 499·165 grammes; salts, 23·064 grammes; carbon, 303·75 grammes; and nitrogen, 14·8 grammes. The diet of those consuming parboiled rice was calculated to consist of proteids, 93·565 grammes; fats, 45·882 grammes; carbohydrates, 492·540 grammes; salts, 24·335 grammes; carbon, 302·34 grammes; and nitrogen, 15 grammes. The outbreak of beri-beri cannot therefore be attributed to deficiency in the diet issued, either in respect of proteids, fats, carbohydrates, or salts. The rices supplied were of uniformly good quality, and were obtained in quantities sufficient for one month at a time. No evidence was obtained to show that any article of food other than white rice was a possible source of a causative agent of the disease. As some persons had suggested that beri-beri was due to the effects of intestinal parasites, especially ankylostomes, examinations were made to ascertain the proportion of the coolies under observation who harboured these worms, but it was found that the percentage of persons harbouring ankylostomes among the sufferers from beri-beri was practically the same as the percentage among the whole of the persons under observation. The conclusion is therefore that ankylostomes play no part in the causation of beri-beri. Upwards of 1000 systematic examinations of blood were made to try to discover the presence of any organism likely to have a causal relationship to the disease, but without positive result. The authors, therefore, repeat their strong opinion that beri-beri as it occurs in the Malay Peninsula has its origin in white rice, or at least has an intimate relation with that article of diet. Samples of the rices employed in the inquiry were taken daily during the period of the experiment and submitted to exhaustive chemical analyses and microscopic examination. This portion of the investigation is still in progress, and we are informed that the results will be published in a subsequent number of the Studies from the Medical Research Institute, and that they will also form the basis for a further investigation which it is proposed to undertake.

THE RE-EDUCATION OF THE WILL IN THE TREATMENT OF DRUG HABITS.

IN the treatment of inebriety and similar drug habits so much attention has been given to the details of institutional care and to the contending claims of the many medicinal agents which are supposed to have remedial virtues that there has been some tendency to lose sight of the fact that the condition to be dealt with is at bottom a disorder of the will, and that it can only be really cured by restoring the patient's power of self-control. Impressed by the practical inconvenience of this neglect of the psychic element in dealing with these cases, Dr. W. Oscar Jennings, whose name is familar to the medical world as a leading authority on the subject of morphinomania, has published an extremely interesting pamphlet on the re-education of the will in the treatment of the morphia habit. Dr. Jennings insists on the fact that psychical treatment is so essential that even the best conceived physiological remedies will fail to do all that they should if they are not seconded by influences that act on the patient's mentality; and he attributes to this cause the want of success which has been met with in treating the morphia crave by alkalines and toni-sedative remedies. This point, which, of course, has to be considered in the treatment of practically all diseases, is naturally of the greatest importance in connexion with disorders where there is a predominant mental element. But it is not merely as affecting the action of medicines that this mental factor has to be taken into account; it has an even more potent influence on the efficacy of treatment by restraint. For, as Dr. Jennings judiciously remarks, when the weaning from any drug habit has been effected, not by re-education and restoration of the will, but by compulsion, this compulsion is very apt to excite a latent hostility which remains as a subconscious fixed idea to revive at some moment of weakness under the guise of a return of craving. This is undoubtedly the reason why restraint fails to produce a lasting cure in many cases of drug addiction, and it shows the extreme importance of accurate psychological study in dealing with patients of this sort. The method of psycho-analysis may, in fact, be as valuable in treating such drug-slaves as Freud has shown it to be in the re-education of the victims of hysteria. In a larger work, to which this pamphlet is designed as an introduction, Dr. Jennings proposes to illustrate by the exhaustive study of a number of cases the way in which this rebuilding of the will can be effected by the intelligent cooperation of the patient and the physician. Meanwhile his suggestive remarks may be a useful reminder to the advocates of compulsory restraint that very often in matters of conduct no less than in matters of thought

> "He that complies against his will,
> Is of his own opinion still."

POISONOUS FISH IN CHINA.

IN the *Archives de Médecine Navale* for July Surgeon-Major Oudard describes a serious outbreak of "alimentary intoxication" which occurred on board the French battleship *Alger* while stationed in Chinese waters. The place where the event happened is not precisely stated, but we gather from the context that it was Shanghai. 70 men in all were almost simultaneously affected, the symptoms being nausea, vomiting, violent colic, diarrhœa, heart weakness, accentuated chilliness followed in a few hours by considerable elevation of temperature, dilatation of pupils, and partial suppression of urine. Only one death took place, the deceased being a young man who had previously suffered from a renal disorder. By a process of exclusion the cause was traced to the ingestion of a fish that was served for dinner at 6 o'clock in the afternoon. The first case came for treatment about 8 o'clock, the remainder following at brief intervals all through the night. Some cases were more severely affected than others, but all were grave, necessitating the employment of powerful remedies, including ether, caffeine, and artificial serum injections. It was the first case that subsequently proved fatal. The man had been transferred to a hospital on shore, and a post-mortem examination was made there at Surgeon-Major Oudard's request. Nothing in particular was found, only "the ordinary lesions of an alimentary intoxication." Portions of the deceased's organs were sent to the municipal laboratory for examination, but the results were negative. The report, which was in English, stated that "no trace of arsenic was found, and careful search failed to reveal the presence of any other metallic poisons." When forming his diagnosis Surgeon-Major Oudard states that he was influenced by the total absence of the cutaneous eruptions which are of such frequent occurrence in poisoning by damaged aliments, as well as by the fact that most of the cases made their appearance between 8 and 11 o'clock—that is to say, while digestion was proceeding actively. According to the Rev. Father Courtois, who was the director of the museum at Zi-Ka-Wei, the incriminated fish was the *Coroina sina* of Cuvier, belonging to the genus *Soiænidæ*, natural order *Aoanthopterygii*. Another authority, the Rev. Father Gaudar, who has been a missionary in China for more than 40 years, informed Surgeon-Major Oudard that the *Corvina sina* is common in the valley of the Yang-tse, where it is known as Hô Toên, which means "the sucking pig of the canal." It abounds in the canals of the region and its flesh is white and tender, hence the name. It is eaten by the lower orders only, who are careful to remove the genital organs and all eggs before they consume it and also to subject it to prolonged cooking. In some specimens of the fish, which Surgeon-Major Oudard procured shortly after his experience of the effects it produces, the genital apparatus was very largely developed.

THE committee of the proposed Home of Recovery for Patients Convalescent after Surgical Operations has received the magnificent donation of £100,000 from Mr. Ernest Frederick Schiff in memory of his brother, the late Mr. Alfred George Schiff, who died last year. It is reported that the committee has already acquired a large modern house, standing in extensive grounds at Oxshott, Surrey, to convert it to the purposes of the home.

WE deeply regret to announce the death of Dr. Arthur Foxwell, physician to the Queen's Hospital, Birmingham, and professor of therapeutics in the University of that city, upon the morning of August 4th, from the results of a cycling accident. We shall publish an account of Dr. Foxwell's career in a later issue.

Dr. A. Newsholme, principal medical officer to the Local Government Board, and Sir Malcolm Morris have been appointed delegates of His Majesty's Government to the International Congress on Leprosy to be held at Bergen from August 16th to 19th.

THE Departmental Committee appointed to inquire into the law relating to coroners and coroners' inquests and into the practice of coroners' courts has issued its first report with minutes of evidence and appendices.

THE library and rooms of the Royal Society of Medicine will be closed during August for cleaning and alterations.

THE QUINCENTENARY OF LEIPSIC UNIVERSITY.

ON July 29th and 30th the University of Leipsic celebrated the 500th anniversary of its foundation. This seat of learning owes its foundation, five centuries ago, to the fierce rivalries in the University of Prague which in 1409 resulted in the German students leaving the Czechish nation in possession of their Bohemian University. Westwards went the voluntary exiles to found a new home on more congenial soil at a centre where already the great cross-roads of early European traffic had made Leipsic a seat of international trade. To-day the stately Augusteum, the Pauliner Kirche, and the vast congeries of scientific institutes that line and flank the Liebigstrasse are the outward and visible signs of that material progress that marks the extraordinary development of academic Leipsic. The fame of Leipsic as a great intellectual and commercial centre, and as the city linked with the names of Leibnitz, Lessing, and Goethe, is world-wide. After divine service in the University church at 9 o'clock on Thursday morning, July 29th, the academic proceedings were opened, under the ægis of King Friedrich August of Saxony, in the New Theatre, with the "Jubel ouverture" of Weber. The wise men, who had come not only from the East but from every point of the compass, paid their tribute of praise and presented their congratulations to the King, in his capacity of Rector Magnificentissimus of the University which on that day celebrated its 500th anniversary. The scene was stately and picturesque. The court and civic and academic authorities were all represented. Nearly 60 universities sent delegates, they came even from China and Japan. The Saxon Government gave a dinner to 1000 guests in the evening. On Friday, July 30th, the events of the day were such as to tax the best energies of the representatives. First an address of over an hour's duration in the University by the aged yet vigorous Professor W. Wundt, known to all students of psychology; then the announcement of honorary degrees, and then an adjournment to see the students' great procession, representing in the form of a stately pageant the history of the University of Leipsic, in which several hundred students in appropriate old-world costumes took part—a long picturesque procession, it took over an hour to pass any one point. Every convenience was arranged for the guests, while Leipsic itself was crowded with sight-seers. A short interval for repose; then came for some a concert in the Gewandhaus and for others classical plays in the theatre. Towards 9 P.M. the inevitable "kommers," when 10,000 students and their guests assembled to greet the King, the professors, and the staff—to smoke, to sing, to listen to speeches, to rehearse the stories and doings of student days long gone by—all to the accompaniment of an endless libation of beer. Toasts and rounds of applause made the rafters of the large and spacious "Festhalle," constructed for the occasion, ring and reverberate again and again until long after the "wee short hour ayont the twal." By night, or rather in the early morning, the streets were festive with jubilant youths in their gay gala costumes. The whole city threw itself into the spirit of the *Jubiläum*, as it is called here, and supported the celebration in a manner at once magnificent and appropriate, and with a prodigal hospitality. Saxony knows full well what it owes to its University, and is proud of the sons of that famous *alma mater* which has flourished on the banks of the Pleisse during half a thousand years.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 6th, 1831.

ACADEMIE DE MEDECINE DE PARIS.

ADJUDICATION OF THE MONTHYON PRIZES.[1]

To M. Courtois, for his discovery of iodine, 6000 francs.

To M. Lugol, for his successful application of *iodine* to the treatment of scrofulous diseases, 6000 francs.

To M. Coindet, for having been the first to use *iodine* in glandular swellings, 4000 francs.

To M. Amussat, for his researches on the *torsion* of arteries, 6000 francs.

To M. Leroy d'Etoilles, for his improvements *on* the lithontritic apparatus, 6000 francs.

Lastly, to M. Felix Hatin, for his invention of an instrument for the ligature of nasal polypi, 1000 francs.

---

[1] By a coincidence there appears in the *Times* Literary Supplement of Thursday, July 29th, 1909, the following interesting paragraph under the heading of "Notes on New Foreign Books":—"AUGET DE MONTYON. Par L. GUIMBAUD. Emile-Paul. 7f. 50c. [It was time that a real life should be written of the eighteenth century *bourgeois* who made himself immortal by the foundation of the French Academy prizes which bear his name, and which, if they have not exactly been an incitement to virtue, have made many virtuous people happy. In this matter poor Montyon during his lifetime had to meet with a good deal of ridicule; his notion of recompensing virtue by a prize of money was regarded as absurd by his contemporaries. But the Academy willingly accepted his donation, and *Les Prix Montyon* are to this day very eagerly competed for, and have been the occasion of some of the finest discourses ever uttered under the historic cupola. M. de Montyon's life is well worth reading, especially when one realizes that, born in 1733, he actually lived till 1820, and thus formed a unique link between the old and the new *régime*.]" The name was spelt either Monthyon or Montyon.

ANNUAL REPORT FOR 1908 OF THE METROPOLITAN ASYLUMS BOARD.

WE are indebted to the courtesy of Mr. T. Duncombe Mann, clerk to the Metropolitan Asylums Board, for a copy of this report, which has just been issued. From a preliminary note appears that, although statistical reports had been published by the chairman of the Board at irregular intervals from the year 1871 onward, no regular record of the work of the Board was published before 1886, but that ever since that year a complete report has been issued annually.

The work of the Metropolitan Asylums Board consists very largely of the isolation and hospital treatment of infectious disease, and in this respect it is closely related to the public health work of the Administrative County of London, for the areas dealt with by these authorities are for the most part the same, so that the reports of the Metropolitan Asylums Board may be *considered supplementary to those of the medical* officer of health of the London County Council, and both documents may be consulted together with advantage by those who are interested in the public health and sanitary administration of the metropolis. Although the average daily number of patients under treatment last year was in excess of the average in the previous year by 485, the expenses of the Board showed a decrease of nearly £14,000, as compared with the year 1907. The following table taken from the report, shows the total number of patients admitted to the fever hospitals of the Board during the year 1908, together with the diseases from which they were suffering, and the proportional mortality from the several diseases:—

Diseases	Admissions.	Deaths.	Mortality, per cent.
Scarlet fever	19,629	520	2·56
Diphtheria	5,230	507	9·73
Enteric fever	509	80	16·28
Typhus	2	—	—
Cerebro-spinal meningitis	3	1	40·0
Other diseases	2,594	147	5·68
Total	27,967	1255	—

The managers again congratulate the Board upon the immunity from small-pox which the metropolis has enjoyed throughout the past year, only one case of the disease having been admitted during that period. This patient was a man, aged 36 years, vaccinated in infancy, marks upwards of a square inch in area, four scars less than half foveated; he had not been revaccinated. It is interesting to note that of the 72,691 patients admitted into the small-pox hospitals of the Board from 1870 to 1908 (a period of 38 years) no fewer than 61,806 were received during the five epidemic periods of 1871–73, 1876-78, 1881–82, 1884–85, and 1901–02. Of the remaining 10,885 small-pox patients the years 1879–80 were accountable for 3610 admissions, and the years 1893–94 for 3493, the balance of the cases received during the remaining years ranging from a maximum of 941 in 1895 to a minimum of one in 1908. These figures show that whilst in the first 15 years of the Board's existence the metropolis was visited by small-pox every third or fourth year, in the succeeding 23 years these visitations have only occurred every seventh or eighth year.

The variation in duration of residence of recovered patients at the hospitals of the Board is striking, for it ranges in scarlet fever cases from 60 days at the Eastern Hospital to 72 days at the North-Western Hospital, and in diphtheria cases from 51 days at the Brook Hospital to nearly 72 days at the North-Eastern Hospital. It would be instructive to know the cause of these wide differences, for it is difficult to believe that the type of disease, especially in the case of scarlet fever, has varied so greatly in the same year and in contiguous areas as to require so much longer isolation in the North-Western than in the Eastern Hospital

The report contains important statistics with reference to cases of mistaken diagnosis. In the course of last year 2594 patients, or 9·3 per cent., of the total admissions, were found not to be suffering from the diseases for which they were admitted to hospital. The percentage on the total scarlet fever cases was 6·1, of the total diphtheria cases 22·2, and of enteric fever cases 39·1. Among 1202 cases wrongly certified as scarlet fever there were 97 of measles, 46 of rubella, 280 of tonsillitis, 267 of erythema, and 274 of other, or unrecognisable, disorders. Among the 1159 cases wrongly certified as diphtheria there were 51 of measles, 802 of tonsillitis, and 84 of some other ailment. Among the 199 cases wrongly certified as enteric fever there were nine of influenza, 11 of general tuberculosis, 32 of pneumonia, and six with regard to which no obvious disease could be diagnosed. In the case of small-pox the original medical certificate is revised by a medical officer of the Board at the London wharves. During the year eight persons were certified as suffering from small-pox and were removed to the wharves. The diagnosis was confirmed in one instance only, and the others were returned to their homes.

The Medical Supplement to the report contains particulars of the results of antitoxin treatment of diphtheria during the last four years, as compared with the results obtained before the use of that treatment. From a *diagram there given we learn that whereas in the four years* 1890–93, before the introduction of serum treatment, the average diphtheria mortality in the Board's hospitals was 30·4 per cent.; in the four years 1905–08 the mortality was only from 9 to 10·9 per cent. Several tables are added showing the results of serum treatment at all the hospitals of the Board during the past year, with special reference to the day of the disease on which treatment began. Of 202 cases treated on the first day of the disease there died 3 per cent., whereas there died, of 1076 cases treated on the second day, 6·5 per cent.; of 1182 cases treated on the third day, 10·5 per cent.; of 832 cases treated on the fourth day, 12·7 per cent.; and of 1249 cases treated on the fifth day and later, 14·8 per cent.

In order to increase the limited accommodation for isolating infectious cases at present existing in the Board's hospitals, the "cubicle" or "box" system has been adopted at the South-Western and at the North Eastern Hospitals. Dr. F. Foord Caiger explains that each of the cubicle wards at the South-Western Hospital contains 16 cubicles, which are separated from one another by partitions 7 feet high, of which the upper halves are of glass, the lower halves of silicon plaster. Each cubicle contains one patient only. This system has been found particularly successful in dealing with cases of doubtful character, where newly admitted cases are kept under observation until the nature of the disease has become manifest. Obviously the real test of the value of cubicle isolation is the proportion of patients who develop a second infectious disease while resident in the ward. The medical officers of both these hospitals speak favourably of the system and give particulars of the results obtained. There seems to be satisfactory evidence of the comparative safety of treating scarlet fever patients in cubicles in the same ward with patients suffering from other diseases, provided that care is exercised in carrying out the process The same is true of German measles and also of enteric fever, and statistics are given in proof of these statements.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on July 22nd, Dr. F. H. CHAMPNEYS being in the chair.

A letter, from an approved midwife inquiring as to quarantine to be imposed on pupils coming from hospitals of the Metropolitan Asylums Board was further considered, and a letter from the clerk to the Board on the same subject was also considered.

The Board decided (1) that the reply to the midwife be that in the opinion of the Board safety will not be ensured unless there is (*a*) adequate disinfection before leaving a fever hospital; (*b*) a period of quarantine lasting one week to safeguard patients against incubation of a fever in the nurse. (2) That the clerk be thanked for his letter and informed that the Board notes that, by General Regulation 14 of the Metropolitan Asylums Board's regulations for their nursing staff, nurses leaving service the matron must be [illegible] such nurses has been disinfected.

[illegible] from the Local Government [illegible] opinion as to precautions which [illegible] desires should be adopted by midwives within its jurisdiction in order to guard against the occurrence of ophthalmia neonatorum, and in particular whether the use by the midwife of a weak solution of nitrate of silver is advisable for infants born of mothers suffering at the time of birth from a vaginal discharge. The Board considered that it would not be advisable to order midwives to drop any fluid into the child's eyes as a matter of routine. The Board, having considered the whole question of the precautions to be adopted in order to minimise the risk of the occurrence of inflammation of the eyes in newborn children, decided that the following leaflet be approved, and that, subject to the assent of the Privy Council to the proposed amendments to Rules E 14 and 19, copies be issued to midwives, local supervising authorities, and recognised training schools and teachers :—

[LEAFLET.]

Inflammation of the eyes in newborn children. Ophthalmia neonatorum. This is a very common cause of hopeless blindness, which is one of the greatest misfortunes that can happen to a child. A very large number of children will be saved from blindness if the *following directions of the Central Midwives Board are observed.* It generally arises from purulent discharges from the mother getting into the baby's eyes at birth. It is therefore of "
that this should be prevented: (1) By curing suc
before labour. This requires medical treatmer
as revised). (2) By taking the greatest care that such discharges shall not be carried into the baby's eyes when it opens them for the first time soon after the head is born. The discharges may be carried into the baby's eyes in the following ways: (*a*) The discharges collect round the eyes, especially the eyelashes, and easily get into the eyes. This can be generally prevented if th
hat "as soon as the child's head is born, and if
are opened, its eyelids and the surrounding sk
with clean material such as cotton-wool, lint, or rag, using separate pieces for each eye." The reason for this is that the piece used for wiping the first eye will be polluted by the discharges, and should not be used for the other eye. (*b*) Newborn babies sometimes rub their eyes with their hands. This may rub the discharges into their eyes. As soon as the child is born the hands must therefore be carefully cleansed. (*c*) When the *baby* is bathed the discharges with which its body is covered during labour are washed off into the bath water. If its face is washed in this water, matter may get into the eyes. N.B. The above directions are to be observed in *all* cases, whether purulent discharges are known to be present or not.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on July 29th, Mr. H. T. BUTLIN, the President, being in the chair.

It was resolved to issue diplomas of Membership to 86 successful candidates and, in conjunction with the Royal College of Physicians of London, diplomas in Public Health were issued to 17 successful candidates.

Mr. C. F. Beadles was appointed pathological assistant in the Museum.

On the recommendation of the Museum Committee it was determined to ask Mr. Alban Doran to advise as to the gynæcological specimens in the Museum in connexion with the revision of the pathological catalogue.

A vote of thanks was given to Mr. G. Elliot Smith for his gift of remarkable pathological specimens from Egypt.

On the recommendation of the Committee of Management it was resolved to appoint Mr. R. J. Godlee visitor to the examinations of the Egyptian School of Medicine for the examinations to be held in December next.

The Council resolved to accept the custody of the Odontological Collection formerly belonging to the Odontological Society, on terms agreed upon between the College and the Royal Society of Medicine.

THE MEDICAL SOCIETY FOR THE STUDY OF SUGGESTIVE THERAPEUTICS.—A meeting of this society was held on July 8th, at 20, Hanover-square, London, W., when a paper was read by Mr. J. Walters of Mossley, Manchester, entitled, "Some Observations on Suggestive Therapeutics in General Practice," which was listened to with great interest, as Mr. Walters was able to record considerable success obtained in the treatment of disease by suggestive therapeutics in a great variety of ailments. A discussion followed which tended to show that treatment by suggestion is making headway amongst medical men of the country. All communications relating to the society should be addressed to the honorary secretary, Mr. C. A. Douglas Bryan, Spa House, Leicester.

Public Health.

ANNUAL REPORTS OF SCHOOL MEDICAL OFFICERS.

The City of Hull.—Dr. James W. Fraser is the senior medical officer to the Hull education committee, the chief officer to the committee being Dr. J. Wright Mason, the medical officer of health, who is also immediately responsible for the sanitary supervision of the schools. For the purposes of actual medical inspection there have been appointed six part-time male and two part-time female school medical officers, whose duty it is to visit each school department assigned to them once a week. The examinations thus made do not include tests for sight or hearing, these being carried out by the senior medical officer. As regards the immediate detection of cases of infectious disease amongst the scholars an arrangement is made by which the local school medical officer is liable to be called in by the teacher on any day before 9.30 A.M., and if the cases suspected by the teachers are found to be suffering from an infectious disease they are at once excluded from the school and the medical officer of health forthwith informed of the fact. The school committee has also appointed a whole-time female school medical officer, who, in addition to acting as a part-time medical officer, has to examine any female teachers and bursary holders who prefer the services of a lady doctor, and she has also to take charge of the girls' industrial school, while the senior medical officer has, *inter alia*, charge of the boys' industrial school and examines the sight and hearing of the children in the elementary schools. The head teachers not only weigh and measure the children, but they also test their eyesight with test glasses; while the school nurse, when notified by the head teachers, visits the homes of children suffering from ringworm, scabies, or other skin diseases, and advises the parents thereon. As regards the height and weight of the children Dr. Fraser states that at every age these were in excess of the average given in the official schedule, while only 1·1 per cent. of the children were returned as badly nourished, 82·5 per cent. being normal or good. 23 per cent. of the children examined had enlarged cervical glands, but in only a few instances was it necessary to draw the parents' attention to the matter. In 2·3 per cent. of the children tuberculous disease was diagnosed or suspected, but in only six cases was any lung trouble discovered. As regards the tuberculous condition of certain organs the following comparative table is instructive :—

—	Number examined.	Pulmonary tubercle.	Suspected pulmonary tubercle.	Other lung diseases.	Tuberculous glands.	Enlarged glands.	Bone or joint disease.
Other towns ...	8858	0·65%	—	3·57%	1·6%	13·8%	0·59%
Hull	6856	0·03%	1·2%	3·9%	0·57%	23·1%	0·16%

Dr. Fraser points out that the proportion of tuberculous cases attending school is very small, and he thinks that the explanation of this fact is that when a child is attacked by tuberculous disease it soon becomes seriously ill and is kept at home. In referring to the question of the children's clothing Dr. Fraser states that the physique of the child is often in inverse ratio to the state of the clothing, which seems to suggest that Dr. J. Kerr's explanation is correct—i.e., that the survivors of the slum children are sturdy, while amongst those whose social circumstances are easier many delicate well-clothed children survive. Dr. Fraser thinks that the good nutritional average is due to the fact that Hull, being the centre of a large agricultural and seafaring population, profits in the physique of her children, there being, too, but few cellar dwellings or back-to-back tenement houses. With reference to the subject of treatment, it is found that the parents take their children to their private or club medical attendant or to the infirmary, children's hospital, or dispensary, and in the matter of spectacles a scheme was instituted by the committee three years ago by means of which spectacles ordered by a private practitioner or at the infirmary or dispensary can be obtained at a cheap rate by small payments made to the head teacher, while as regards scabies the school officer is entitled to issue orders for free sulphur baths. Blind children are boarded out at various blind schools after having been examined by the senior medical officer, and when they reach the age of 16 years they are granted maintenance scholarships which enable them to learn basket-making and the like. There is a degree of thoroughness and directness about this city of the north which is inspiring, and instead of talking about difficulties as regards treatment the committee appears to get over them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8294 births and 3397 deaths were registered during the week ending July 31st The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 12·6 to 10·6 per 1000, only increased to 10·8 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these towns averaged only 11·2 per 1000, and in London during the same period it did not exceed 10·7. The lowest recorded annual death-rates last week in the 76 towns were 4·5 in East Ham, 4·8 in Burton-on-Trent, 5·2 in Willesden, and 5·7 in King's Norton; the rates in the other towns ranged upwards, however, to 16·0 in Huddersfield, 16·1 in Wigan, 16·6 in Great Yarmouth, and 18·4 in Rotherham. In London the recorded death-rate last week did not exceed 10·3 per 1000, and showed but a slight increase upon the exceptionally low rate in the previous week. The 3397 deaths from all causes in the 76 towns last week showed an increase of but 61 upon the low number in the previous week, and included 315 which were referred to the principal epidemic diseases, against 341, 324, and 313 in the three preceding weeks; of these, 113 resulted from diarrhœa, 80 from measles, 48 from whooping-cough, 41 from diphtheria, 25 from scarlet fever, and eight from "fever" (principally enteric), but not one from small-pox. The 315 deaths from these epidemic diseases last week were equal to an annual rate of 1·0 per 1000, corresponding with the rate in each of the two preceding weeks. No death from any of these epidemic diseases was registered last week in Gateshead, Brighton, Plymouth, Swansea, Northampton, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·7 in Walsall, 4·0 in Newport (Mon.), 4·3 in Warrington, and 5·9 in Stockton-on-Tees. The deaths attributed to diarrhœa in the 76 towns, which had increased in the four preceding weeks from 49 to 90, further rose to 113 in the week under notice, and caused annual death-rates equal to 1·6 in Rotherham, 1·7 in Birkenhead, 2·6 in Bury, and 2·9 in Stockton-on-Tees. The fatal cases of measles, which had been 138, 114, and 95 in the three preceding weeks, further declined to 80 last week, the highest death-rates from this disease being 2·1 in Walsall, 2·9 in Stockton-on-Tees, and 3·3 in Newport (Mon.). The 48 deaths from whooping-cough also showed a further decline from the numbers in recent weeks; the highest death-rate from this disease last week was 1·1 in Huddersfield. The 41 deaths referred to diphtheria, however, exceeded the number in any recent week, and included 22 in London and its suburban districts, four in Liverpool, and two each in Nottingham, Derby, and Bradford. The 25 fatal cases of scarlet fever showed a decline from recent weekly numbers; they included eight in London and its suburban districts, three in Manchester and Salford, and two each in Liverpool, Warrington, and Halifax. The deaths referred to "fever," which had been 22 and 11 in the two preceding weeks, further declined last week to eight, a lower number than in any recent week. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2737 and 2731 on the two preceding Saturdays, had further declined to 2667 on Saturday last; 296 new cases of this disease were admitted to these hospitals during last week, against 415 and 367 in the two preceding weeks. The registered deaths in London last week referred to pneumonia and other diseases of the respiratory organs, which had been 108 and 132 in the two previous weeks, declined again last week to 106, and were 15 below the corrected average number in the corresponding week of the five years 1904-08. Only three deaths in London were directly referred to influenza last week, corresponding with the average. The causes of 33, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered last week were again duly certified in London, Leeds, West Ham, Bradford, Newcastle-on-Tyne, Leicester, Nottingham, and in 52 smaller towns; the 33 uncertified causes of death included six in Liverpool, three in South Shields, and two each in Birmingham, Hull, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS

In eight of the principal Scotch towns 892 births and 423 deaths were registered during the week ending July 31st. The annual rate of mortality in these towns, which had been equal to 12·5 per 1000 in each of the two preceding weeks, further declined to 11·8 in the week under notice. During the first four weeks of the current quarter the death-rate in these Scotch towns averaged 12·4 per 1000; in the 76 large English towns the mean death-rate during the same period did not exceed 11·2. The death-rates last week in these Scotch towns ranged from 10·2 and 10·3 in Paisley and Aberdeen, to 15 2 in Leith and 18·8 in Greenock. The 423 deaths in the eight towns last week showed a further decline of 25 from the numbers returned in recent weeks, and included 39 which were referred to the principal epidemic diseases, against 36, 40, and 45 in the three preceding weeks. These 39 deaths were equal to an annual rate of 1·1 per 1000, against 1·1 and 1·3 in the two preceding weeks; the rate last week from the same epidemic diseases in the 76 large English towns was equal to 1·0 per 1000. Of the 39 deaths last week from these epidemic diseases in the Scotch towns, 15 resulted from whooping-cough, 13 from diarrhœa, four from scarlet fever, three from measles, three from "fever," and one from diphtheria, but not one from small-pox. The fatal cases of whooping-cough, which had been 16 and seven in the two preceding weeks, rose again to 15 last week, of which five occurred in Glasgow, five in Edinburgh, and two both in Leith and Greenock. The 13 deaths attributed to diarrhœa showed a decline of one from the number in the previous week, and included six in Glasgow and two each in Edinburgh and Paisley. The four fatal cases of scarlet fever slightly exceeded recent weekly numbers; two were returned in Glasgow and one each in Edinburgh and Dundee. Of the three fatal cases of measles, fewer by 11 than those in the previous week, two occurred in Edinburgh and one in Paisley. The three deaths referred to "fever" corresponded with the number in the previous week, and included two in Dundee (of which one was a fatal case of typhus), and one in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had declined from 76 to 49 in the four preceding weeks, further fell to 43 in the week under notice, but exceeded by two the number returned in the corresponding week of last year. The deaths in the eight towns last week included 17 which were referred to different forms of violence, of which nine occurred in Glasgow, four in Edinburgh, and two in Dundee. The causes of 20, or 4·7 per cent., of the deaths in the eight towns last week were uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 16·9 and 14·4 per 1000 in the two preceding weeks, rose again to 17·4 in the week ending July 31st. During the first four weeks of the current quarter the death-rate in the city averaged 16 1 per 1000, whereas the mean rate during the same period did not exceed 10·7 in London and 12·9 in Edinburgh. The deaths of Dublin residents from all causes last week showed an increase of 23 upon the number returned in the previous week, and included 15 which were referred to the principal epidemic diseases, against 11 and nine in the two preceding weeks. These 15 deaths were equal to an annual rate of 2 0 per 1000, the death-rate from the same epidemic diseases last week being equal to 0·8 in London and 1 5 in Edinburgh. Of the 15 deaths from these epidemic diseases in Dublin last week, five resulted from diarrhœa, four from measles, four from whooping-cough, and one each from scarlet fever and diphtheria, but not one either from "fever" or small-pox. The five deaths attributed to diarrhœa only exceeded the number in the previous week by one, but the fatal cases both of measles and whooping-cough showed a marked increase. The 133 deaths at all ages included 23 of infants under one year of age and 31 of persons aged upwards of 60 years; the deaths of elderly persons showed an increase. Eight inquest cases and five deaths from violence were registered during the week; and 46, or 34·6 per cent., of the deaths occurred in public institutions. The causes of all but one of the deaths registered in the city last week were duly certified, showing a proportion of but 0·8 per cent.; in London the causes of all the 957 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was equal to 6·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: H. W. G. Doyne to the *President*, additional, temporary, and C. L. W. Bunton to the *Carnarvon*, on recommissioning. Staff-Surgeons: M. P. Jones to the *Topaze;* M. C. Langford to the *Devonshire*, on commissioning; M. Cameron to the *Attentive*, on recommissioning; F. J. L. P. McKenna to the *Leander*. Surgeons: J. J. H. Rooney to the *Vivid*, additional, for disposal; C. F. Bainbridge to the *Devonshire*, and A. V. J. Richardson to the *Hampshire*, both on recommissioning; F. G. H. R. Black to the *Carnarvon*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

The following is a list given in the order of seniority of officers on the Indian establishment who will be tour expired during the trooping season of 1909-10:—Lieutenant-Colonels: F. P. Nichols, F. J. Jackson, W. Pike, E. H. L. Lynden-Bell, J. R. Stuart, G. Wilson, W. C. Beevor, S. F. Freyer, J. R. Forrest, H. A. Haines, G. E. Hale, D.S.O., W. T. Swan, C. T. Blackwell, P. C. H. Gordon, H. D. Rowan, H. Cocks, F. W. G. Gordon-Hall, A. Kennedy, H. P. G. Elkington, H. M. Adamson, A. R. Aldridge, D. M. O'Callaghan, R. Holyoake, F. S. Lequesne, V.C., and A. L. F. Bate. Majors: E. A. Burnside, B. J. Inniss, R. C. Thacker, A. J. Luther, H. E. Winter, J. W. Jennings, D.S.O., C. Dalton, C. W. Duggan, T. McDermott, H. W. K. Read, J. B. Anderson, E. S. Clark, K. M. Cameron, M. Boyle, F. Kiddle, J. Grech St. J. B. Killery, G. T. K. Maurice, W. E. Hudleston, and M. McG. Rattray; Captains: C. H. Hopkins, J. G. Berne, G. B. Carter, S. O. Hall, J. H. Brunskill, A. J. Hull, A. B. Smallman, W. F. Ellis, S. M. W. Meadows, T. E. Harty, B. G. Patch, D. P. Watson, J. E. Powell, F. M. M. Ommaney, R. H. MacNicol, S. L. Pallant, C. R. Sylvester-Bradley, J. D. Richmond, M. C. Wetherell, H. C. Hildreth, W. MacD. Macdowall, R. T. Collins, T. J. Wright, A. C. Osburn, F. J. Turner, J. Fairbairn, J. H. Douglass, R. R. Lewis, A. L. Otway, F. H. Noke, W. F. H. Vaughan, R. B. Hole, T. C. Lucas, G. E. Cathcart, W. Wiley, H. Harding, J. A. Turnbull, M. F. Grant, M. D. Ahern, F. J. Garland, A. A. Meaden, S. C. Bowle, and A. S. Arthur.

Lieutenant-Colonel Samuel F. Freyer, C.M.G., retires on retired pay (dated August 4th, 1909). Lieutenant Harry R. Edwards, from the Seconded List, is restored to the establishment (dated July 30th, 1909).

TERRITORIAL FORCE.

Royal Garrison Artillery.

Glamorgan: The undermentioned officers from the 2nd Glamorganshire Royal Garrison Artillery (Volunteers) are appointed to the unit, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Major John Lynn Thomas, C.B., Surgeon-Captain Robert John Richard Cobden Simons, Surgeon-Captain Charles Octavius Parsons.

Royal Army Medical Corps.

6th London Field Ambulance: Henry King Dawson to be Lieutenant (dated July 6th, 1909).

For Attachment to Units other than Medical Units.—Captain William Starbuck Griffith, from the Sanitary Service, to be Captain (dated March 1st, 1909). William Evelyn Alston to be Lieutenant (dated July 1st, 1909). The appointment to a Lieutenancy of William Henry Newton bears date Feb. 21st, 1909.

Attached to Units other than Medical Units.—Lieutenant Alfred L. Low resigns his commission (dated March 31st, 1909). Captain Alexander P. Swanson to be Major (dated Nov. 23rd, 1908). Captain Martin A. Cooke to be Major (dated June 20th, 1908). Ivan Cochrane Keir (late Lieutenant, 4th Battalion, The Duke of Edinburgh's (Wiltshire Regiment)), to be Lieutenant (dated July 1st, 1909).

ROYAL ARMY MEDICAL CORPS EXAMINATIONS.

The following are the successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London, for which 54 candidates entered:—

	Marks.
G. H. Dive, St. Bartholomew's Hospital, M.R.C.S., L.R.C.P. ...	632
L. C. Hayes, Birmingham University, L.R.C.P. Lond., M.B. Birm.	597·5
B. G. Goodwin, Birmingham University, M.R.C.S., L.R.C.P. ...	584
A. S. Cane, Cambridge University and St. Bartholomew's Hospital, M.R.C.S., L.R.C.P.	563
T. H. Dickson, Edinburgh University, M.B., B.Ch. Edin. ...	547
K. Comyn, Cambridge University and King's College Hospital, M.R.C.S., L.R.C.P., B C. Camb.	542
F. R. Laing, Edinburgh University, M.B., B.Ch. Edin.	539
A. G. Jones, Guy's Hospital, M.R.C.S., L.R.C.P., M.B., B.S. Lond.	536
J. M. Weddell, Cambridge University, M.R.C.S., L.R.C.P. ...	535
P. C. Field, Bristol and Guy's Hospital, M.R.C.S., L.R.C.P. ...	528
V. P. Hutchinson, Guy's Hospital, M.R.C.S., L.R.C.P.	518·5
T. W. Stallybrass, Newcastle-on-Tyne, M.B., B.S. Durh. ...	514·5
H. G. Robertson, Glasgow University, M.B, B.Ch.	513·5
R. C. G. M. Kinkead, Queen's College, Galway, M.B., B.Ch. R.U.I.	511
C. M. Nicol, Glasgow University, M.B., B.Ch.	
H. V. Stanley, Trinity College, Dublin, M.B., B.Ch.	
E. C. Stoney, Sir P. H. Dun's Hospital, M.B., B.Ch.	510·5
A. P. O'Connor, Catholic University, M.B., B.Ch. R.U.I. ...	507·5
R. N. Davies, Durham University, M.B., B.S.	506
R. Gale, Glasgow University, M.B., B.Ch.	505

INDIAN MEDICAL SERVICE EXAMINATIONS.

The competitive examination for commissions in the Indian Medical Service was held on July 26th, 27th, 28th, 29th, 30th, and 31st, for which 48 candidates presented themselves for 21 vacancies. The subjects of the examination were medicine and therapeutics, surgery and eye diseases, pathology and bacteriology, surgical anatomy, physiology, midwifery and diseases of women and children, pharmacology, and toxicology. The following is a list of the successful candidates. The aggregate of marks was 5100.

	Marks.
Charles Harold Smith, Liverpool University, M.D., Ch.B., F.R.C S. Eng., L.R.C.P. Lond.	3997
Alan MacDonald Dick, Edinburgh University, M.B., Ch.B., L.R.C.P., M.R.C.S.	3740
Thomas John Carey Evans, University College, Cardiff, and St. Mungo's College, Glasgow, L.R.C.P., M.R.C.S., M.D. Brux.	3733
Robert Inglis Binning, Glasgow University, M.B., Ch.B. ...	3712
Maurice James Holgate, St. Bartholomew's Hospital, M.B., B.S. Lond., L.R.C.P., M.R.C.S.	3512
John McDougall Eckstein, St. Bartholomew's Hospital, L.R.C.P., M.R.C.S.	3503
Trevor Laurence Bomford, St. Bartholomew's Hospital, M.B., B.S. Lond., L.R.C.P., M.R.C.S.	3471
William Andrew Morton Jack, St. Thomas's Hospital, M.B., B.S. Lond., L.R.C.P., M.R.C.S.	3433
Graham Rigby Lynn, St. Bartholomew's Hospital, M.B., B.S. Lond.	3412
Louis Hope Lovat Mackenzie, Cambridge University and St. Thomas's Hospital, M.B., B.C., L.R.C.P., M.R.C.S	3404
Alexander Charles Anderson, St. Thomas's Hospital, L.R.C.P., M.R.C.S.	3385
Duncan Gordon Cooper, Edinburgh University, M.B., Ch.B. ...	3366
William Leonard Forsyth, Glasgow University, M.B., Ch.B. ...	3333
Keshav Sadashiv Thakur, Lahore Medical College and University College Hospital, L M. & S. Punjab	3288
Mohamed Abdur Rahman, Guy's Hospital, L.R.C.P., M.R.C.S.	3281
Framroze Jamsetjee Koleporewalla, Grant Medical College, Bombay, and Guy's Hospital, L.R C.P., M R C.S.	3258
Herbert Robert Burnett Gibson, Edinburgh University, M.B., Ch.B.	3257
David Arthur, Glasgow University, M.B., Ch.B.	3252
Edw[illegible] [illegible]e University and St. [illegible]	3225
Ger[illegible] Hospital, M.B., B.S. [illegible]	3187
Rus[illegible]ty College Hospital, L.M. & S. Bombay, L.R.C.P., M.R.C.S.	3143

A TRIBUTE TO SIR JAMES MCGRIGOR.

As we announced in our last issue the statue of the late Sir James McGrigor, Bart., first Director-General of the Army Medical Department, has been removed from the Chelsea Hospital to the new Royal Army Medical College in Grosvenor-road. The August issue of the *Journal of the Royal*

Army Medical Corps contains an appreciative biography of the late Director-General from the pen of Lieutenant-Colonel M. W. Russell, R.A.M.C., illustrated with a portrait and a reproduction of an imposing obelisk, which was originally erected to the memory of Sir James McGrigor, Bart., in the quadrangle of Marischal College, Aberdeen, but which is now in the Duthie Park, Aberdeen. In the same issue Captain N. E. Harding, R.A.M.C., contributes some extracts from "Miscellanies" of Sir James McGrigor, and there is a list of the subscribers who contributed to the memorial which now adorns the quadrangle between the officers' mess and the commandant's quarters of the Royal Army Medical College. This list is accompanied by an excellent reproduction of the statue.

"Audi alteram partem."

THE NATURE OF ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—Reading in THE LANCET of July 31st the necessarily condensed but interesting *résumé* of Sir T. Clifford Allbutt's remarks in opening the discussion on Angina Pectoris at Belfast causes me to regret that I was prevented at the last moment attending the meeting to take part in the discussion, when I should have had the advantage of hearing the whole statement, which possibly dealt more fully with some of the points I am about to mention. I do not, however, desire to occupy any of your valuable space for a general discussion of the subject, but in order that I may make my own position in the matter more clear, as Sir Clifford Allbutt's courteous reference to my views which you publish scarcely represents them quite accurately. According to your report (p. 337) he there states my conception of the cause of angina pectoris to be a lesion of the "intracardiac ganglia."

In speaking thus Sir Clifford Allbutt doubtless had in view my remarks upon a case of intravascular coronary aneurysm published in THE LANCET (Vol. II., 1902), in the neighbourhood of which there was an intravascular collection of nerve cells in the intima of the vessel—that is to say, in a position, so far as I know, not recognised by anatomists as innervated—and I certainly believe that in this case they might reasonably be regarded as having some relation to the pain evinced. For, while I am aware that physiologists at present regard peripheral visceral ganglia as only motor in function, I contend that our knowledge on this point is insufficient to maintain that this is invariably the case, and the *situation* of the ganglion in question renders it difficult to conceive for it a merely motor or nutritive purpose. But intravisceral or intravascular ganglia, if a source of pain in some cases, are only *one* source of angina, and I can conceive no reason why a certain degree of stimulation of the cardio-vascular nerves in any portion of their course from Sir Clifford Allbutt's "suprasigmoid" area downwards, should not likewise be capable of originating the pain with or without an actual breach of surface. The chief factors in the production of such stimulation may therefore, I would suggest, be the plus or minus action of the cardiac muscle according as it is hypertrophied or degenerated, the impaction of a foreign body in the coronary vessels, which an ante-mortem clot essentially is, or disturbance or lesion of the aorto-cardiac nervous system. The constant character of the process or syndrome is to be attributed to the constant anatomical and physiological nature of the stimulable cardiac nerves.

Apart from the question of the *source of the pain* in angina, I am glad to find myself in accord with Sir Clifford Allbutt in regarding the *cause of death* in such cases to be an inhibition of the cardiac action by that shock to the nervous system which either induces rapid death in diastole, as proved by necropsy, or such a depression of the contractility of the organ (to use a term descriptive of a phenomenon rather than denotative of a vital action) as kills after a longer interval, during which, while death is approaching certainly, pain is usually absent owing to the fall of blood pressure attending a failing heart. In his experience of complete and permanent recovery from what used to be called angina vera and which it is sometimes convenient, if illogical, to use clinically still, Sir Clifford Allbutt has been more fortunate than myself. While I have known the affection to be apparently in abeyance for long periods, my own experience is that angina once established, so as to leave its diagnosis indubitable, death from cardiac failure due to local conditions and with or without pain is the rule—a fact which argues a local source of the affection. But the experience of angina by individual observers differs, and the holding of this discussion in Belfast reminds me that that prince of cardiologists in his day, William Stokes of Dublin, in his memorable work, published in the ripeness of his experience in 1854, states that [illegible] with a case! It is, moreover, [illegible] Registrar-General's reports show [illegible] ways been a disproportionately small, as there is in Scotland a disproportionately large, death-rate from angina pectoris as compared with that occurring from the same cause in England.

I am, Sir, yours faithfully,
ALEXANDER MORISON.

Upper Berkeley street, W., August 1st, 1909.

*** In our report of Sir Clifford Allbutt's remarks at Belfast we referred to his theory as having been first published in part in 1894. This statement was not quite correct. Sir Clifford Allbutt then advanced the same hypothesis in its entirety as he continues to uphold.—ED. L.

A CERTIFICATE OF THE CAUSE OF DEATH FOLLOWED BY AN INQUEST.

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. Edwin J. Toye, is scarcely justified in his statements in THE LANCET of last week. He there remarks, "As a matter of fact, the medical man has no such discretionary power. It is obligatory upon him to certify the cause of death even if violent." He then gives part of the 20th section, leaving out these words:—

> [illegible] information of the death, deliver [illegible] the cause of death shall be entered [illegible] e name of the certifying medical [illegible]:

It is quite clear that the medical attendant of the deceased person is not required to give a certificate unless the death be from natural causes, and such as the registrar may accept without hesitation and enter upon the register. To give the cause of death as due to violence would be waste of time and trouble. In the 39th section of this same Act the refusal to give a certificate is only enforced when this is done "without reasonable excuse." When there is one the medical attendant has a discretionary power and it is his duty to refuse to certify and to refer the case to the coroner. Moreover, the 3rd subsection of Section 20 runs thus:—

> Where an inquest is held on the body of any deceased person a medical certificate of the cause of death need not be given to the registrar, but the certificate of the finding of the jury forwarded by the coroner shall be sufficient.

When this Act was passed in 1874, coroners acted upon the ancient statute of 1 Edward III., stat. 1, c. 8. This required the coroner to go to the place where any be slain or suddenly dead or wounded, to summon a jury, and to inquire as to the cause of death. Acting upon this coroners claimed the right to hold an inquest in any and every case of sudden death, even though its cause was well known to the relatives and to the medical attendant. The 3rd section of the Coroners Act, 1887, passed just 13 years later than the Act quoted by Dr. Toye, requires the coroner to hold an inquest in every case of violent or unnatural death, or sudden death the cause of which is unknown. There is thus no difficulty in determining when to give and when to refuse a certificate. Should the medical attendant have any doubt, it is clearly his duty to refer the case to the coroner, with whom rests the responsibility of deciding whether there is reasonable cause to suspect that the death is one of those I have named. What is required is to avoid useless inquests involving the attendance of twelve jurors at great inconvenience to themselves. Writing from an experience of 44 years as a witness and looker-on, I have no hesitation in confirming what was stated in your annotation of July 24th. Dr. Coley was perfectly within his right when he gave a certificate of the cause of death of his patient, and the coroner was not justified in holding an inquest without first conferring with Dr. Coley. There is now no "crowner's quest law," but there is the law of the land which governs coroners as well as medical attendants. The whole subject is now prominently before the medical profession and the public, and it is the duty of all members of the profession, individually and collectively, to maintain their rights.

I am, Sir, yours faithfully,

Liverpool, August 2nd, 1908. FRED. W. LOWNDES.

THE MERCURIAL TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I am interested in the article by Dr. J. E. Squire and Mr. J. A. Kilpatrick, on Pulmonary Tuberculosis Treated by Deep Muscular Injection of Mercuric Succinimide, in THE LANCET of July 17th, p. 141. I have been using the injections in similar cases according to Wright's latest technique, which omits the two weeks' course of potassium iodide. I would not give the iodide, as I did not think the results would be as good. I have had to discontinue the injections in nearly every patient because of the acute pain following them in thin subjects and the occurrence of a lump of the size of a walnut at the site of the injection after an injection or two, no matter whose preparation I used. I found that the physical signs improved and the patients felt better under the treatment; one patient felt so well that he did more than he was fit for and sent his temperature up. I am inclined to think that some patients are more sensitive to the reaction of the mercury than others, and that the mercury also has a share in sending the temperature up. The initial effect I found was to reduce the temperature and night sweats. Only one of my cases was sensitive to the mercury, and as he was an ex-pressman he probably did too much. I only used the mercury injections in advanced cases, those which I could not use tuberculin in. I was disappointed at being forced to discontinue the treatment from the causes I have outlined, so have put them all on hydrarg. iodid. viride by the mouth, and later will report my results.—I am, Sir, yours faithfully,

A. J. ANDERSON, M.B., C.M. Edin.

Newport, R.I., U.S.A., July 24th, 1909.

THE DRINKING CHILD.

To the Editor of THE LANCET.

SIR,—Dr. Imre Doczi, the representative of the Hungarian Government at the Twelfth International Congress on Alcoholism, read a paper on Alcohol and its Effects upon the Child. The original paper was written in his native tongue, and was subsequently translated into German and thence into English, with the result that an unfortunate error crept in, and he was made to say in the published abstract that: "As a result of statistics gathered it is found that there are hardly any schools in which there is a pupil who is a total abstainer. On the other hand, it is by no means rare to find schools where there are not pupils who do not have alcohol given to them in some form by their parents." He has requested me to ask you to correct the error and to state that what he intended to convey was that: "Most carefully prepared statistics based upon the data obtained by the Hungarian Government as to the drinking habits of all the children—i.e., about half a million children under the age of 18—in all the schools of all classes, both elementary, private, and public, show that 20 per cent. of the children are total abstainers. It is by no means rare to find schools where pupils are given alcohol daily by their parents. Among the poor Slav population this is given in the form of spirits distilled from grain, or possibly more commonly from potatoes."

The investigation was carried out in a very thorough manner and it was found that 36 per cent. of the pupils who indulge in alcoholic drinks were careless and idle; 11 per cent. dull of comprehension; 13 per cent. incapable of prolonged attention; 10 per cent., during the first hours of the morning (from 8 to 9), gave confused answers; 18 per cent. were very backward in subjects requiring special mental effort; while only 10 per cent. showed no ill-effects. The statistics show, further, that alcohol has a marked influence on mind, character, and bodily health. In only 3 per cent. of the cases had a medical man prescribed alcohol for the child.

These facts may be taken as valuable evidence of the necessity for similar research in England. Some months ago I obtained figures from a few of the London County Council infant schools, and found that, in each, no less than 40 per cent. of the infants under eight years of age drank alcohol more or less regularly. There appears to be no doubt that a similar state of things exists in every part of Christian Europe except in the countries of the farthest north, and it would be interesting to find out whether the figures I obtained from schools chosen haphazard are true of the rest of the country. In one school of some 300 infants I found that 11·8 per cent. drank alcohol daily, 34·1 per cent drank occasionally, and 54 per cent. were "Band of Hope," but I know of one "Band of Hope" child in another school who drinks alcohol daily.

The medical inspectors of school children already have power to obtain this information, and it is to be hoped that during the course of the next few years some such inquiry will be made into the drinking habits of the children in this country. I am, Sir, yours faithfully,

F. G. MACKERETH.

Beulah Hill, Norwood, S.E., July 28th, 1909.

CHILDREN'S COUNTRY HOLIDAYS FUND

To the Editor of THE LANCET.

SIR,—August is with us. All the hoardings display attractive programmes of holiday excursions. But for the vast majority of the child population the beautiful pictures that accompany them conjure up no happy memories of green fields and golden sands. The elementary schools are closed, and they are doomed to spend their month's holiday in the streets or playing in dark courts.

The Children's Country Holidays Fund is trying to help as many of them as possible to realise the meaning of the pictures by aiding them to spend a fortnight's holiday in country cottages. Last year 42,510 were sent away. On July 22nd this year 22,000 went away and are now being entertained right royally by their cottage hosts. Arrangements have been made and homes found for 23,000 more. Only one thing is lacking—the necessary money. At present subscriptions show a falling off of nearly £1000, and at least £8000 are required if none of them are to be disappointed.

May I appeal to your readers who are either holiday-making or preparing for their holiday to give generously, so that the required sum may be promptly made up? The cost is small, the benefit to the child great. 10*s* will pay for the holiday for one child. All contributions, large or small, should be sent to the honorary treasurer, the Earl of Arran, 18, Buckingham-street, Strand, W.C, who will gratefully acknowledge them.

Yours faithfully,

July 30th, 1909. A. F. LONDON.

THE ROUTINE USE, BY THE OPEN METHOD, OF A MIXTURE OF CHLOROFORM AND ETHER.

To the Editor of THE LANCET.

SIR,—The method adopted by Dr. F. Hewitt and Dr. J. Blumfeld of dismissing all my contentions by disagreeing with the least important struck me as a little too "cavalierly" to be passed over in silence, for the fact that my practice agrees with (so far) uncontroverted theory, while theirs does not, surely entitles my arguments to some further consideration than was shown in their general reply; and I maintain that the routine use of C_2E_3, simple and unmodified, is not sufficiently safe, that it is likely to cause anxiety even to skilled anæsthetics, and that it may be very dangerous in the hands of the practitioner who, giving anæsthetics seldom, will indubitably take Dr. Hewitt's and Dr. Blumfeld's article to mean that in C_2E_3 he has *it*—Panacea.

The use of this mixture as a routine is good because simple, but it has only its simplicity to recommend it, and if safety can be added to simplicity by the "simple complication" of adopting the "open ether" method, what grounds does the rejection of a good working theory give for condemning the improvement in method?

To advocate any method of giving chloroform (to give C_2E_3 *is* to give chloroform) which does not provide for a diminishing dose is in these days a retrogression, and in so far self-condemnatory. And this for two reasons, each becoming almost daily plainer and better understood. These are: (1) the not infrequent occurrence of "status lymphaticus"; and (2) the ever-present danger of delayed chloroform poisoning.

1. It is said that status lymphaticus cannot be recognised ante-mortem. I do not agree. In my experience it never does to give much, if any, chloroform vapour to persons under 30 years of age who (1) have some enlargement of the thyroid gland with fulness of the episternal notch; (2) have a slow pulse with no spring or rebound in it; and (3) are either not apparently nervous or are in a mournfully depressed state. They may seem to be excellent subjects for anæsthetics in every other way, but if they present those signs they are always *the worst*. But there is no particular danger and not much anxiety if the C.E. mixture be limited in quantity and followed by open ether. 2. Delayed chloroform poisoning can (only) be prevented.

I beg leave to endorse Dr. Barton's remarks on the value of C.E.—ethyl chloride—C.E. sequence for rapid (and safe) induction, such value being obvious in the case of children and nervous women, and enhanced by the fact that patients who are caused to "go under" quickly also "come round" quickly—and pleasantly—a point of some importance in private work.

I am, Sir, yours faithfully,

London, S.W., August 3rd, 1909. DONALD J. MUNRO.

AN INDEPENDENT MEDICAL PROFESSION IN INDIA.

To the Editor of THE LANCET.

SIR,—The question of fostering the development of an indigenous medical profession involves two considerations, inter-related indeed, but yet vitally distinct. The first and incomparably the more important is, what ought and what can Government do to promote the growth of a body of medical practitioners trained indeed in Government colleges of medicine but dependent thereafter, not on Government employment, but on private practice amongst their fellow countrymen. The second and much narrower question is to what extent it is possible or desirable to utilise native agency in Government medical work, whether legal, educational, clinical, or research. It is on the solution of the former question that depends the gradual extinction of that farrago of Hippocratic pathology, occultism, and empiricism that constitutes the stock-in-trade of the hakim, the vaid, and the Ojha, and that leads to the vast mass of suffering, loss of health, and premature death which all must deplore who know anything of medical practice in the East. In this matter the policy of Government has been to provide a Western medical education of a higher and lower grade and to establish far and wide charitable dispensaries staffed by native practitioners primarily for the direct relief of suffering amongst the poor but also as an object-lesson to the well-to-do in the benefits of Western medicine. The lesson has been but too well learnt and the effect has unfortunately been the pauperisation by free medical aid of a vast number of the comparatively well-to-do and the direct discouragement of the private practitioner. Our medical diplomates, like those in arts and law, now look for a career almost solely to Government employ. The remedy is difficult to indicate but will probably be found along two main lines, the imposition of some check on abuse of charity together with some restriction of unqualified practice. But whatever be the remedy it cannot be too much emphasised that this is the important and outstanding question—namely, the status and prospects of the private practitioner—and any solution of our second question must be judged mainly by its probable bearing on the first.

Let us turn now to the second question. It is admitted that up to the present the most responsible Government work, whether connected with research, with medical education, or with forensic medicine, has been entrusted to members of the Indian Medical Service. And this is so for reasons which must be held to be to a great extent still valid. For fruitful research the worker must be in close touch with the trend of scientific thought and experiment. At present India is a back-water far removed from the main current of scientific activity. The worker in India therefore must be in close touch with Europe and that in the nature of things the Indian graduate cannot yet be in any sufficient measure. Nor, it must be confessed, is there any evidence as yet of any aptitude in the Indian mind for original research in this realm of thought.

In the same way, until there arises something like a national school of medicine in India, it is necessary that the principal *teaching* should be in the hands of those who are by association and training fitted to be the channel through whom new methods and new views from more advanced centres may find their way into Indian practice. And even a European-trained Indian graduate does not fulfil this condition. More important than original training as a student is often renewed contact with the Western schools. Any attempt unduly to curtail the influence of European teaching in the medical schools of India will inevitably lead to stagnation, if not retrogression. That important medico-legal work should be largely in the hands of Europeans depends on the same cause that leads Government to retain the principal judicial posts largely in the hands of the Civil Service. While cordially admitting the great improvement in knowledge, ability, and honesty of the Indian medical practitioner, as of the native magistrate, we may still maintain that it will be long yet before the average native practitioner, however skilful, can be trusted to be as independent as his European *confrère*.

One reason, perhaps the most important reason, for the existence of the Indian Medical Service in its civil branch is apparently considered unworthy even of mention—namely, to afford medical aid to the European officers of Government and their families. Apart from any statutory right which such civil servants may be able to urge, it is obvious that morally one of the first duties of any civilised Government in a tropical, semi-civilised country is to afford its servants such assistance in sickness as they would be able to command at home—just as the parallel duty is recognised of assisting to provide the ordinances of religion.

It must be remembered that the qualifications of the vast majority of native practitioners are not such as would entitle them to registration in the United Kingdom. Even were their qualifications above reproach, the difference in social customs and manner of life of the two races is such as will always entitle the European civil servant, and more especially his family, to the services of a medical officer of his own class and colour. But what are "the more important civil surgeoncies" to which it is proposed to appoint natives? Precisely those where there are the largest official European communities and in which, whatever the Secretary of State and his advisers may think, their own civil servants will undoubtedly and most justly insist on having a European medical attendant of their own class.

I forbear to dwell on the effect on the service of any attempt to carry these views into effect. But it is sufficiently obvious to anybody who knows anything of the feeling of the service as to the already greatly diminished advantages of civil employ, that if only to the more isolated stations, where social amenities and professional prospects are least and unpaid drudgery greatest, are appointments to be open, there will be the greatest difficulty in filling even this numerically restricted cadre from the ranks of the service. Government would be better advised to devote its attention to the encouragement of the private medical practitioner, on the one hand, and, in the sphere of State medicine, to the crying need of a properly organised native sanitary service. Between the two all the surplusage of Indian-trained graduates may be for many a year to come usefully absorbed. Nor should the rewards and honours in these spheres be beneath the deserts of even the most distinguished.

I am, Sir, yours faithfully,

July 25th. FURLOUGH.

THE TERRITORIAL MEDICAL SERVICE.

(FROM A SPECIAL CORRESPONDENT.)

II.—THE SELECTION OF SITES FOR CAMPS, WATER-SUPPLIES, &C.

BEFORE actually proceeding to a camp of exercise, much useful work can be done by a Territorial medical officer in the nature of making inquiries, either in person or by correspondence, from the local military authorities of the area in which it is proposed to locate his unit for field training. As a general rule the actual site of the camp, if on War Department ground, is selected and allotted to the different units by the local military authorities (G.O.C.), and his staff medical officer (A.M.O.) is responsible for the sanitary administration. Inquiry should be made from the latter, or in his absence from the local medical officer of health, as to the prevalence of infectious diseases in the vicinity of the camp and of the arrangements to be made for treating cases of infectious disease occurring during a training. The writer has known considerable flutter to have arisen in a large Volunteer camp where a case of small-pox occurred, no such inquiry having previously been made. A map of the camp area should also be obtained and definite instructions from the local A.M.O. as to the camp conservancy arrangements, more especially the standard types or plans with full directions for latrines, urinals, sullage water, and grease pits, and whether latrine seats have been provided for officers and N C.O's. The water-supplies of the camp should be inquired into, whether if wells or springs they have been protected from surface pollution and fenced round, the arrangements for providing R.A.M.C. water squads, water- and filter-carts and instructions for cleansing them, also whether it is necessary that the water should be clarified, filtered, or boiled, and the provision of materials (alum, fuel, &c.) for carrying out this. The question of provision of an incinerator for the camp and also proper ablution benches for the men should not be lost sight of. A few days before the departure of the main body to camp the sanitary squad under their N.C.O. should be sent with the advance party. Definite instructions should be issued to this party by the O.C. unit as to the position and number of latrines, urinals, urine pits, sullage, and grease pits to be dug. not forgetting the latrines, &c., for the canteens and institutes. Lastly, the address of the engineer officer (O.C. R.E.) of the camp area should be ascertained, as he is the responsible official for remedying constructional defects, water-supply, drainage, roads, &c. During camp training every attempt should be made by senior medical officers to instruct their juniors in all matters appertaining to the relationship of sanitation and preventive medicine generally to the art of war. In this country the medical profession is very much behindhand in the matter, whereas on the continent the standard literature on the subject is very full. It is understood that the War Office authorities are at present engaged in the preparation of a handbook.

The more military medical officers understand of tactics and strategy the greater will their appreciation be of any given situation and the more will their advice on sanitary matters be recognised by general officers. In peace time any training, medical, sanitary, or otherwise, to be of value must be on the lines that will be followed in actual war, and the question of the selection of grounds for encampments and bivouacs will naturally be one of importance, and one of the greatest possible factors in the prevention of disease among troops on field service will be strict attention to all matters relating to camp hygiene.

An army in the field encamps or bivouacs with the primary object of obtaining rest and food, the degree of enjoyment of which depends on security of repose from the enemy's attack, and also on the quality, quantity, and facility of obtaining food- and water-supplies; and last, but not least, upon the sanitation of the ground occupied and its continuous upkeep.

Rules for Selection of Site.

In time of war the site for a *standing* camp is selected chiefly because it presents certain strategical advantages, and will be, as a rule, found on lines of communication and other places more or less of a permanent nature. The site for a *temporary* camp, on the other hand, is chosen on account of some tactical advantage which the ground may offer, and for this reason the comfort of the troops occupying it may often have to be much more neglected than in the case of standing camps. Nevertheless, the nature of the ground on which men have to sleep should, if possible, always be considered, as if men have to rest on damp or very uneven, stony ground, their rest, and consequently their health, will suffer. Some military leaders, Napoleon for instance, considered bivouacs more healthy than living in tents. Bivouacs, however, have one great disadvantage—namely, the difficulty of the men getting undisturbed sleep. In the selection of a site for a camp or bivouac three main considerations may be said to be involved: (1) Security against attack from the enemy; (2) convenience for roads and water; and (3) sanitation. With the first of these—namely, security—a medical officer has no official responsibility, but when detailed alone or detailed to accompany an advance guard or reconnaissance party, he should bear it in mind when looking out for a likely site. With the second consideration, that of convenience of site, a medical officer has an official advisory interest; and with the third consideration, or that of sanitation, the medical officer is the official of all others who does and should bear the full brunt of responsibility.

In all cases of selection of camps, a medical officer (either the Sanitary Officer, Army Headquarters, when the camp is intended for the main army, or the sanitary officer of a division, if the camp for such is under consideration) should accompany the combatant staff officer sent forward, and an officer of the Royal Engineers should also be present if possible, as some details connected with water-supplies, drainage, or the like, may require his special and individual attention. Such representatives must be regarded as experts, who will examine the proposed site from different points of view according to their own branch of the service, and the opinion of each should be weighed as circumstances allow when the final selection is made. No officer of this committee should be detailed to choose a camp on his own initiative alone, as, assuming each to be an expert in his own particular line, he will be an enthusiast, and enthusiasts may at times be dangerous, being liable to be more or less prejudiced in favour of their own special profession. Selection by a mixed quorum will always be found a wise precautionary measure, from the fact that it will neutralise any such tendency. "When military and sanitary decision in the selection of a camp clash, as they may frequently," says Lord Wolseley, "the point must be settled according to their relative importance in each case. If a great battle is impending everything must give way to strategical or tactical exigencies of the moment, and troops may have to bivouac for many nights in positions that may be objectionable in a purely sanitary point of view. It may, however, be accepted as a general rule that when beyond two days' march of the enemy sanitary conditions are to be accepted first.

The special sanitary officer who aids in the selection of a camp site must take into consideration the following points; he should also be in a position to make a concise written report on each if necessary.

1. Fitness of the site in point of salubrity as to soil and subsoil, shape of ground, nature of cultivation, suggestions as to best form of camp, and precautions necessary for its sanitary conservancy.
2. Water-supplies, their quantity, quality, and precautions necessary for their upkeep, distribution, and protection from pollution.
3. Position of latrines, cook-houses, and refuse trenches.
4. Local supply of provisions and fuel.
5. Roads leading to camp, and means of lateral communications.

Fitness of the site in point of salubrity.—In selecting the site of a camp the following suggestions as to its general salubrity may be considered. One of the most important points to remember is to avoid encamping on ground that has been previously occupied as a camp, if possible, and if this is unavoidable for military reasons, go as far to windward as possible of the old site. Should an army be obliged to occupy a defensive position for any length of time on which an attack is expected to be made, pitch the camp or bivouac in advance of such position, so that when the enemy approach the vicinity clean ground can be retired on if necessary and your adversary is forced to occupy a polluted site for his own camp should he move to attack you. Similarly, when water-supplies come under consideration always camp up-stream and protect your water-supply. Avoid camping near marshes; the banks of running rivers are good. The presence of an abundance of green vegetation generally indicates a damp and more or less unhealthy locality, but such places should be noted and borne in mind in the event of water being scarce, as by digging or boring wells or by sinking Norton's tubes in such places water can probably be obtained. A grass country with sand or gravel as a subsoil, which acts as a natural drain, is the best possible site for a camp; especially is this the case if the ground is level and on the top of a rise or ground gently sloping to the east or south. Sites on granite, metamorphic, clay-slate, and trap-rocks are also good, unless these rock strata be disintegrated, when they are unhealthy; limestone and magnesian limestone sites are also healthy when not marshy, and although the water-supplies are hard they are good. Chalk strata by themselves, when unmixed with marl, are good, and so is the water in their vicinity. When, however, marl and chalk exist together they usually form impermeable strata and the soil is damp and water-logged. Permeable sandstone sites are generally most healthy. Avoid flat country lying below sloping ground, and low-lying meadow land. Land with a clayey or marl subsoil is damp and becomes unbearable in wet weather: the ground becomes a bog; men's feet, blankets, and clothing become wet—so such soil should be avoided. The shade of the trees, either in camp or near at hand, is of great value in sheltering men and animals from the sun; but decaying vegetation, jungle, and forests recently cut down are all dangerous in tropical and malarious countries.

Selection of Water-supplies for a Camp.

Having considered the fitness of the site of a camp in point of salubrity as to the soil and subsoil, and the main features of the ground with reference to its shape and general position, the next point to consider is the facility it affords for obtaining water, wood, and forage. As the subject of water-supplies is of greatest importance it will be considered first. The presence or absence of water will on all campaigns compel a General Officer Commanding to fix the length and direction of his marches and almost dictate the plan of campaign. It was the absence of a proper water-supply that compelled General Buller to give up the hope of relieving Ladysmith after the successful battle of Vaal Krantz. It was on account of the want of a proper water-supply that the Duke of Wellington was compelled to occupy a position at the action of Vimiera which he had to change almost at the moment the French attacked. So a sanitary survey of water-supplies will always be a matter of the greatest importance in war, and in reporting on a water-supply in war time the first factor is "quantity"; if this is sufficient the question of "quality" can be gone into. The permanency of water-supplies when they come from springs or wells is a matter of importance. In a flat country the permanency of a spring is doubtful unless the water is very cold; this will indicate that it comes from deep strata; on the other hand, springs from the foot of hills are, as a rule, permanent. In districts where sandstone strata exist springs are usually permanent, as such strata are subject to the formation of subterranean reservoirs from the action of carbonic acid in the rock. There are usually few springs in chalk districts on account of the porous nature of the soil; below chalk strata springs may exist. In granite and trap districts all forms of small streams are suspicious as to permanency unless they originate in lakes, otherwise they are very variable as to [illegible] is selected it should be [illegible] safe from pollution by the [illegible] on above its water-supply. This is of great importance when a camp is to be occupied for more than one night; if it has unavoidably to be occupied longer construct a drain to intercept any possible pollution between the camp and the water-supply. When it is necessary to search for water by borings they should be made at low levels in a plain, or in places where long rank grass exists or where vegetation is more luxuriant, such as the low levels, at or near the bottom of hills, at the junction of dry or damp water courses of two or more valleys, or where mist rises in the evening, or under cliffs, or under the highest side of a valley. The sanitary officer having selected the water-supplies they should at once be marked with distinguishing flags (and put in charge of water-guards) for drinking, watering animals, bathing, and washing; a red flag should denote water for drinking, a red-and-black for watering, and a black flag for bathing and washing. If the supply is derived from a running stream [illegible] to prevent men from washing [illegible] above the drinking-water [illegible] he flags should at once mark out the water; above the first or red flag the water for drinking and cooking to be drawn; between the red and the red-and-black flags horses and cattle to be watered; between the black-and-red and black flags bathing; and below the black flag washing of clothes. When drinking water has to be obtained from a river with high banks, buckets should not be used, but a light hand pump with a hose. The hose should have a strainer attached to the end of the suction pump; the water can then be pumped into tarpaulin sheet baths, and mud, if present, allowed to settle. On no account should men be allowed to dip their water-bottles in such water-supplies, as they only stir up the mud; they should be made to draw it from water carts which can be filled from the tarpaulin by means of a hand pump. When water has to be taken from a pool the same system ought to be adopted, and when it has to be taken from a broad dry river bed small wells should be dug a few feet from the edge into which the water will filter through the sand. The water can be taken from these by pumps; by this means the main supply is untouched and not disturbed.

In standing camps the approach to the intake from a river or stream should be roughly paved and the surface in its vicinity cleared of bushes and rank vegetation. The stream should, if necessary, be slightly deepened at the intake and all weeds removed. If required, a small dam should be thrown across the river just below the intake. If several pools or wells are used, drinking water wells should be selected at a higher level than watering, and watering at a higher level than washing or bathing. Neither surface nor subsoil pollution should be permitted in any place where it is likely to pollute the drinking water. For this reason water for washing purposes is to be pumped off by a light hand-pump and hose or, failing this, drawn in buckets and used some distance away at a place indicated by a black-and-white flag. When bathing is indulged in men are not to use soap, and when clothes are washed they are to be washed at the black-and-white flag. This is an arrangement of the first importance both for health and comfort, and when a position is to be occupied for any length of time these regulations are of still greater moment.

If the water-supply is from springs, small reservoirs should be made to catch and hold the supply that runs off during the night, so that every gallon of water may be available; or barrels may be sunk with gutters connecting each to receive the overflow as each is filled. A small well with a limited supply can be improvised by sinking a barrel perforated all round with half-inch holes; from this the water can be easily drawn. The surroundings of this well should first be thoroughly freed and cleansed of all vegetation, dead leaves, and débris; a clear area of at least 20 yards' radius should be railed off to prevent contamination, and no troops or animals should be allowed in the vicinity. All water from such wells ought to be drawn in clean metal buckets, or better still, it should be pumped by a light hand pump with a protected suction hose into a tarpaulin bath sheet, and again from this into water carts. In the selection of wells the water should be analysed if possible, and the inhabitants living in the vicinity closely questioned as to its pureness and permanency. Wells that dry up in the hot weather months should be rejected in favour of permanent ones; preference should also be given to wells that are in a good state of repair and not overhung by bushes or rank vegetation; their position as regards freshly manured fields and villages must also be considered. In standing camps wells should be thoroughly cleaned out and as much water as possible drawn off before being taken into use, and water should never be drawn except by pump or metal bucket. The surface ground in the immediate vicinity of a well should be drained to carry away all water spilled.

No water should be judged from chemical or bacteriological tests alone; it is also necessary to see its source and course and also use common sense. If chemical tests are not available, next to smell, taste, and ordinary common sense, a fair estimation can be made of water in a well by attention to the following points:—The construction of the well, the source of water and its depth, its immediate surroundings, and its relation to obvious pollution. The meteorological conditions prevailing when the water is examined must be remembered, and it must be ascertained if any specific water-borne disease is supposed to exist in the locality.

When a large pond, tank, or reservoir has to be used for drinking purposes as well as watering animals and where pumps are not available, the supply for drinking purposes should be obtained as far away as possible from the places where the animals are watered or washing done. Animals should water from the shallow side of a pond and a pump should also be connected here, if possible, leading to a trough for washing purposes. Water for drinking should be drawn from the deepest part and be pumped out if possible. In all cases sentries must be posted over the water-supply, and it should be laid down as a rule that the captain and subaltern of the day on duty for each battalion must visit during their tour of duty the sources from which the water is supplied to their men and see that no irregularities take place there. It is also advisable that the field officer on duty and the orderly medical officer of the day pay surprise visits to see that the conservancy of these water-supplies is being maintained, and an officer should accompany all watering parties. In arranging the common water-supply of a camp, where there are several divisions, an understanding must be arrived at by the staff officers of each division as to the guards to be mounted daily over the water and the regulations to be enforced.

Drinking water should, if possible, only be taken from sources which are above suspicion. If such sources are not available we must of necessity attempt purification by means of filters or boiling. The simplest, most suitable, and most certain means is boiling. Permanganate of potash is useless unless employed in very large quantities. Sterilising tablets are not suitable for the British soldier. Bisulphate of soda is generally unserviceable, but for short, *forced* marches not exceeding three days it should prove valuable; after a few days' use it acts as a purge. Ozone as a purification agent acts very well and will possibly be the steriliser of the future; it is, however, expensive to generate. For troops on service the following line of water prophylaxis seemed to be indicated from our experience in recent wars: (1) Griffiths or Forbes Waterhouse sterilisers for troops in standing camps; (2) candle filters with preliminary strainers carefully protected by packing in baskets and carried on trained mules for troops on the line of march; and (3) bisulphate of soda tablets for forced marches of not more than three days. Whether sterilisation be employed or not, as soon as time and labour are available all water-sources should be improved and new ones of irreproachable character selected and established.

In calculating the amount of water necessary per man for drinking and cooking, six pints should be the minimum allowance in temperate, and eight pints in tropical, countries per diem. The maximum quantity required for all purposes will not exceed five gallons per head except in hospitals, where eight ought to be allowed. The following is the daily allowance for animals: elephants, 25 gallons; camels, 10 gallons (these animals are not regular drinkers); horses, oxen, mules, and ponies, five gallons each. (Horses, oxen, mules, and ponies drink one and a half gallons at a time and take at least three minutes to drink every time they are watered.) In calculating water in bulk it may be useful to remember one cubic foot of water contains six gallons. The transport for carrying water is very great and also very costly when it has to be brought for any distance. During the military operations at Suakin 13,000 gallons of water required 700 camels to accompany the force that went to Hasheen. During the operations in Natal all the water required at Frere had to be moved by train in railway water-tanks from down country, and at the battle of Colenso these water-trucks supplied the troops with water on the field of battle. In the Soudan campaign, at the advance depôt and at the base, the iron tanks used for holding water on board ship were used. A sanitary committee assembled at Cairo during this war, considering the various patterns of water-carrying appliances, gave it as their opinion that iron tanks were at all times preferable to wooden ones for either storage or transport of water, and recommended their use for the Suakin expedition.

Filters.—No existing type of filter suitable for field service appears to be free from the danger of becoming a focus of infection; most of the filters tried in the field in recent years are all too liable to choke with mud and become too slow in delivery, others are too complicated in their mechanism, easily injured in transport wagons, and require time to set up and work. When they arrive in camp they are generally too late for the companies that should march out on night picket before the wagons get in. The filters used by troops, British and continental, for the last few years have all been of the candle type, such as the Pasteur-Chamberland, Mallie, and Berkefeld, all of which can efficiently sterilise water in standing camps and with troops under conditions of peace, but, generally speaking, have not proved satisfactory in the field when used with a *moving* field army, as breakage or cracking of the candles so often occurred. The candles are also very prone to loosen at their attachment and leakage then occurs, allowing unfiltered water to pass through and mix with the filtered. Another objection to such filters is the frequent necessity to clean them, as the filtering medium, the candle, gets clogged and water will not pass through until it is brushed, and brushing and sterilising bougies not only wear them out but cause minute cracks which impair their germ-stopping properties. Filters which require daily sterilisation are impracticable for motile columns on field service. Berkefeld filters were supplied extensively to the South African Field Force in the late war, and proved most efficient when carefully husbanded by intelligent workers who understood what their purpose was intended for, and who clarified water with alum preparatory to filtration, thus avoiding clogging with mud; but it is only in places like standing camps, hospitals, or officers' messes that the instructions, as laid down in the directions that accompanied each filter, were carried out, and even in such places constant supervision was necessary. The Berkefeld filter is much more rapid in its delivery, but is not so durable as either the Mallie or Pasteur-Chamberland, neither is it so efficient, as the porosity of the candles is greater. In multiple bougie filters, where more than one candle is used, experience has proved that they are very unreliable, as breakage, cracks, or flaws of one or more candles are of so frequent occurrence that the probability of leakage is always present, so that the purity of the water has to be frequently tested by bacteriological examinations, which are often impossible on field service. We may sum up the disadvantages of all bougie or candle filters as follows: (1) their delivery is too slow, and this is especially the case when the water is foul and the pressure feeble; (2) the output diminishes in proportion to the length of time the candle is in use, and the filter requires frequent cleaning; (3) the cleaning requires to be carried out by a skilled attendant, using considerable care on account of the fragility of the candles; (4) as it is difficult to notice breakages or cracks which may occur during cleaning and which completely neutralise the good effects of the filter much illusory security exists; (5) these filters are not a success on field service, when they require to be frequently taken to pieces for transport; on the line of march their fittings get loose, and this danger is increased when they have to be entrusted to careless and clumsy hands. Soldiers, in order to get water more quickly, may break the candles to let it run through, and the writer has known instances where the candles were deliberately removed and the water pumped through the outer case for appearances' sake. Recently the French War Department have made exhaustive trials in barracks of the Pasteur-Chamberland filter with André's cleaning apparatus attached with favourable results, but this does not appear applicable for field service on account of the weight and fragility. This apparatus facilitates the use of the filter by removing the risk of breaking the candles and allows cleaning to be entrusted to inexperienced hands, so that the wear and tear is almost *nil*, even after two years' work. André's apparatus is said to increase the output of the candles when the filter is working under pressure, although the original water may contain more than an average amount of impurities. The candles are cleaned by an india-rubber comb worked by a crank, and jets of water play on the candles at the same time. These combs in turn touch every portion of the surface of the candles, and cinder and fine charcoal dust is put in to render the cleaning more certain. Charcoal dust is also put into the filter after cleaning and before refilling it with water. The minute particles of charcoal envelop each candle and form a shield, keeping gelatinous deposits away from the pores of the candles. The most suitable powders are those of Kieselguhr, or ground charcoal refuse.

It is, however, very desirable that officers should have some ideas, before starting a campaign, as to improvised filters, or rather water-strainers, and the means of making them, by converting barrels, oil cans, biscuit tins, and various other utensils into filters, and also the means of improvising and turning to account all kinds of contrivances to suit various purposes. In standing camps, improvised strainers have been made in many ways, of which the following may be mentioned:—1. In the case of muddy pools, wells were sunk at a short distance from the water-supplies and the soil was made to act as a natural filter. 2. Clean, empty beer barrels were sawn in half and a hole a foot square was cut out of their bottoms, and fine cloth, linen, and khaki in several layers were stretched over the aperture. This acted as an excellent strainer for mud. This tub-strainer was placed over another complete barrel, which received the strained water, and this, when finally drawn off by a tap below, came out clear. A lump of alum rubbed round the inside of the barrel when full of water for a few seconds (if the water is very muddy) will hasten the deposit of sediment and will not affect the taste of the water. If desired the water can next be filtered through a Berkefeld filter, through which it will now easily run, and, finally, it may be boiled, as filtration does not do away with the necessity of boiling. If strictly carried out boiling will prevent water being a source of enteric fever and dysentery. Swamp water, or water containing vegetable débris, which gives it a rusty tinge, should always be boiled. Dysentery is especially prone to be produced by it in the tropics—for instance, Burma. Much of the water in Baluchistan and Central Asia is so impregnated with salts as to cause severe diarrhœa. A salty-tasting water favours the growth of cholera germs and must be looked on with suspicion.

Mud never at any time is a favourable adjunct to the food of man and acting as an irritant to the intestinal tract produces an acute gastro-intestinal inflammation, which inevitably results in diarrhœa. Acute gastro-intestinal inflammation easily tends to become chronic; this is especially manifested and aggravated on service when troops are fed on preserved field rations and biscuits. When the [illegible]tion is most grave. From [illegible] r emaciates and becomes [illegible] the mucous membrane of the intestines is such that a suitable nidus is presented to the germs of enteric fever or dysentery should they be present in any further water drunk.

(To be continued.)

QUACKERY AND SECRET REMEDIES IN SWEDEN.

(BY AN OCCASIONAL CORRESPONDENT.)

SWEDEN to-day is a happy hunting ground for quacks whose main grievance must surely be this, that their "profession" is overcrowded. The yearly increasing number of foreign patent medicines with which the country is deluged has led the chemists and medical profession to join hands in agitating for reforms the character of which was discussed in the Swedish Medical Society early this year.

Legislation alone is worse than useless. There are still laws on the statute books which, though unrepealed, are of historical interest only. As early as 1688 the status of both physician and apothecary was clearly defined, and their rights were jealously guarded. Quackery and the sale of secret remedies were as the sin of witchcraft for which the offender had to pay the then ruinous sum of 50 dalers. This fine was equally divided between the College of Medicine and the poor. Repetition of the offence meant a 100 dalers fine plus "exemplary punishment." What this punishment consisted of is not stated: that it erred on the side of leniency is highly improbable considering the spirit of the age. A more recent law enacts that the illegal dealer in medicines dangerous to the life or health of man shall be punished with hard labour lasting from two to ten years. In the eighteenth century an attempt was made to combat the evils of secret remedies by buying and publishing the secret of the inventor. The purchase-money was supplied by the State or the College of Medicine, which must often have made a very poor bargain. A remedy for dysentery proved to consist of rhubarb, nutmeg, and wax; after swallowing this compound the patient was given barley gruel and melted wax. A cure for ague was found to contain cobwebs, rhubarb, and the bark of alder and aspen. The princely sum of £3000 was paid by the State only for the right to import a cancer "cure" which appears to have contained sulphur, arsenic, and powdered ranunculus flammula. This compound was applied to the "cancer" in dry form or mixed with yolk of egg. Patenting of medicines had assumed such proportions in 1856 that a law was passed prohibiting the practice. By registering the name of his "cure" the inventor not only evaded this law but also became entitled to the profits of his invention for ever, whereas on the expiration of a patent, the price of the invention could no longer be arbitrarily fixed. Registration of the name of any preparation was refused when its source, nature, and use were common property. Since 1908, however, this restriction has been removed on international grounds, and the inventor may now register even the names of preparations which are notoriously fraudulent. In face of penalties, drastic enough on paper, the modern quack sells for 10 marks his 88 grammes of cigar ash as a cure for dropsy, for 9.50 marks 4 grammes of boracic acid are dispensed as "philosophic gold salt," and for Kr.8.75 a small quantity of vaseline and tinc. cantharidis is sold as a hair-grower to the bald and beardless. The vendor of this last remedy, however, ran foul of the law in Denmark, where he was forcibly detained. About 1400 letters, value from £200 to £300, were addressed to him at this period.

Under the leadership of Professor Mörner the "Bureau for Information about Medical Advertisements" was started in 1903. This institution, which is subsidised by the Society of Apothecaries, aims at providing the public with gratis trustworthy information as to the composition, action, and real value of advertised remedies. From time to time it publishes the results of its investigations in pamphlet form under the heading, "About Fraudulent Medical Remedies and Methods." A systematic watch is kept over advertisements of secret remedies, which are collected by hundreds and analysed. The bureau is aided by a section of the press in exposing the worst frauds to the public. It is also in touch with similar foreign institutions, the publications of which are collected for reference. The bureau has recently exposed a quack by name Olsen, who spelt his name backwards, and did a roaring trade in "Sequa's rheumatic ointment," the chief constituent of which was vaseline. A portrait of "Dr. Sequa" on the wrapper proved on investigation to be really that of a well-known author. Illustrations of "Dr." Neslo's chemical laboratory were taken from photos of the [illegible] happy slip a number of [illegible] to Neslo's chemical la[illegible] chemical laboratory, which responded by sending out the bureau's pamphlet. Olsen has now abandoned the treat[illegible]is, consisting of [illegible]e embarrassing [illegible]he truth about [illegible] consisted of a "Kr.3 50 a bottle" cure for phthisis styled "Woodjuice." This was composed of 99·85 per cent. water and 0·15 per cent. wax, resin, &c. The bureau stated that the most valuable constituent of the "cure" was the empty bottle.

The exposure of a quack remedy is repeatedly followed by the remedy's reappearance in another and more potent form, but if the cooperation of pharmacists is forthcoming the evils of the traffic in fraudulent cures can be at any rate moderated. An enterprising pharmaceutical chemist has devised the plan of dispensing drugs in a wrapper on which some of the bureau's exposures of frauds are printed. The latest edition of these wrappers for distribution by chemists appeared in an [illegible] The bureau's assistance is some[illegible] journals when these are in doubt [illegible]ccepting certain advertisements.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Meeting of the British Medical Association.

THE seventy-seventh annual meeting of the British Medical Association made Belfast a veritable centre of medical talent during the last week in July. The meeting was a thoroughly successful one both from a scientific and social point of view, and there is no doubt that the State visit to it of the Lord Lieutenant of Ireland and Lady Aberdeen gave the meeting an additional *éclat*.

University of Belfast.

To provide for the expected larger demands upon its resources next session the Senate has sanctioned the expenditure of £1500 on the provision of better equipment for the departments of physiology and pathology, pathological laboratory, physics, chemistry, zoology, archæology, anatomy, botany, and geology. A notice has been issued to graduates of the Royal University of Ireland who are entitled under the Act to join the Queen's University, and an application form for this purpose has now been sanctioned by the Senate and will be sent to any such graduate by the registrar on application. The University contingent of the Officers' Training Corps goes into camp at Ballykinlar on the 31st inst. for a fortnight's training. The Commander-in-Chief in Ireland (Sir Neville Lyttelton, G.C.B.) has expressed his intention of himself making the annual inspection of the corps during their stay in camp.

Vice-Regal Visit to Lurgan.

On Saturday, July 31st, after concluding their visit to Belfast, the Lord Lieutenant and Lady Aberdeen travelled to Lurgan, where the former opened a new park and the latter received in audience the ladies of the Lurgan branch of the Women's National Health Association of Ireland, who presented an address.

Action against Medical Practitioners.

At the recent Belfast Assizes, before the Hon. Mr. Justice Dodd, a smith's finisher sued Mr. John S. Bryars and Mr. Charles A. Mateer (both of Belfast) to recover £1000 damages for personal injuries alleged to have been caused by the negligence and want of skill of the defendants. It appeared that as medical attendant to the Smiths' Society, Mr. Bryars had been called to the plaintiff in May, 1907, and came to the conclusion that he was suffering from a bruise of the left hip due to a fall off a bicycle. Mr. Mateer saw the plaintiff in June of the same year, three weeks after the accident, and came to the same conclusion. Finally, the plaintiff went into the Royal Victoria Hospital, where a radiogram was secured, which, however, showed nothing in the way of fracture. Mr. R. Campbell (who saw the case at the hospital with Mr. Mateer) came to the conclusion that there was a subperiosteal fracture, which was very rare. Mr. T. S. Kirk, thinking there was a fracture, laid the bone open, but found the fragments perfectly in apposition but ununited. He cut away the loose bone, the effect of which was to shorten the leg still further, but it had removed the pain and, in his evidence, Mr. Kirk said that the man would be able to go about his work, though crippled in his walk. The treatment adopted by the medical men previously in attendance did not, in Mr. Kirk's opinion, prevent the union of the bones. The judge said that a mere mistake was not evidence of incompetence on the part of a practitioner. The jury returned a verdict in favour of the defendants and the judge expressed approval of their decision.

August 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Memorial to Professor Paul Brouardel.

ON July 20th a bust of the late Professor Brouardel, who also held the position of dean, was unveiled in the *cour d'honneur* of the Paris Faculty of Medicine. The bust, which is a striking likeness of its original, is a fine work of art in white marble and stands against the wall of the small amphitheatre on one side of the entrance. M. Doumergue, Minister of Public Instruction, took the principal part in the ceremony and there was a very large attendance, including the widowed Madame Paul Brouardel, who sat facing the official dais. Addresses were delivered by M. Thoinot, M. Landouzy, M. Liard, M. Guyon, M. Roux, M. Lereboullet, and lastly, by the Minister. The bust has been executed by Denys Puech; it stands on a tall pedestal ornamented with a design that has become classical—namely, two allegorical figures, one of which holds a wreath of roses.

The Prevention of Eruptions after Subcutaneous Injection of Serum.

At a meeting of the Society of Biology held on July 17th M. Netter said that the giving of chloride of calcium by the mouth for three successive days after the injection of antidiphtheritic serum had a notable effect in diminishing the appearance of troublesome eruptions. In collecting the results of three series of observations he found that among 600 patients who had taken chloride of calcium there were 18 cases in which an eruption followed, or 3 per cent., whereas among 648 patients who had not taken chloride of calcium there were 109 cases in which an eruption followed, or 16·8 per cent. He gave chloride of calcium in doses of 1 gramme per day and continued the administration for three days and even longer if several injections have been performed. In case of necessity it might be given in an enema. The efficacy of the chloride of calcium was much less marked in the case of patients who had received intraspinal injections of anti-meningococcic serum, even though the doses of the chloride were larger than usual and the administration continued for several successive days. The penetration of the tissues by the serum when given intraspinally was no doubt exceptionally rapid and copious.

Pneumonic Plague.

At a meeting of the Academy of Medicine held on July 20th Professor Chantemesse read for Dr. de Brun of Beyrouth a paper on cases of pneumonic plague observed by him in that city. He gave a very complete analysis of the earliest symptoms of this form of plague, these symptoms being almost always of very sudden onset and not presenting the initial rigor. After describing the course of the illness he said that the majority of the patients exhibited agonising terror due to consciousness of their approaching end. Death took place from the third to the fourth day and was accompanied by symptoms of asphyxia which depended more on decomposition of the blood than on changes produced in the lungs and heart. It was quite certain that the bronchopulmonary lesions played no more than a subsidiary part in the symptomatology of the disease and did not account for either its extremely sudden invasion or the phenomena of the fatal termination. In their clinical development these lesions, whether insignificant or urgent, whether slight bronchitis on the one hand or broncho-pneumonia on the other, were uniformly associated with septicæmia—a circumstance which explained the cyanosis observed during the first hours of the illness in patients not yet exhibiting any organic cardiac or pulmonary complication; it also explained the agonising dyspnœa *sine materia*, the intense and early alteration of the features, and the intestinal hæmorrhage. All the symptomatology of the disease unmistakeably indicated the existence of septicæmia, and the bacteriological investigations of Dr. de Brun confirmed this hypothesis by demonstrating the presence of the microbes of plague in the blood as well as by the positive results of cultivation in bouillon and on agar-agar. It might therefore be said that the pneumonic form of plague was in fact a specially septicæmic form, characterised from the clinical point of view by the coexistence of variable pulmonary and bronchial lesions. This view seems to cast a new light on the disease and to suggest ideas which might be turned to useful account in diagnosis.

Treatment of Acromio-clavicular Dislocations.

Discussing the subject of acromio-clavicular dislocations at a meeting of the Surgical Society held on July 21st M. Delbet said that these displacements might assume two forms—namely, either subluxation or complete luxation. In the former case the coraco-clavicular ligaments were intact and the movements of the arm were but little interfered with, whereas in the second case the ligaments were ruptured, with well-marked loss of power as the result. In these circumstances some surgeons have sutured the ligaments, but without much success. M. Delbet tried replacing the ruptured ligaments by silver wires. These, however, broke asunder, and he then used silk threads, which were found to answer very well up to the time of the patient taking his discharge, after which the case was lost sight of.

Vegetable Cookery.

One of the ways of cooking vegetables formed the subject of a communication made by M. Maurel and M. Carcassagne at a meeting of the Biological Society held on July 10th. In this particular method, called *blanchiment des légumes*, the first water was thrown away after the vegetables had been boiled for 35 minutes, the natural consequence being an important loss of mineral constituents. Experiments made by these two observers with several kinds of vegetables, including cabbage, celery, asparagus, and beans, showed that on an average their total saline constituents were diminished by 36 per cent. and their potassium constituent by 50 per cent. after *blanchiment* continued for 30 minutes. As vegetables prepared in this way seemed to be easy of digestion, especially by dyspeptics, the process might be advantageous, especially in cooking for vegetarians.

Occurrence of the Mongolian Blue Patch in a European Infant.

At a meeting of the Société Médicale des Hôpitaux held on July 16th M. Apert showed a suckling infant which had on the lower part of its back a large bluish patch, the colour being deepest at the level of the upper limit of the intergluteal groove, and gradually fading where the patch extended over the lumbar region and flanks. He said that 90 per cent. of the new-born children of the yellow race had a patch of exactly the same kind, and for this reason it had been called the Mongolian patch. It also occurred in new-born negro children, but in them it was very soon masked by the natural black pigment. It was, moreover, a regular characteristic of young chimpanzees, orang-outangs, and many lower simiæ. This patch had been very rarely seen in children of apparently pure European extraction. It was doubtful whether its appearance in such circumstances indicated retrogression in racial type or ancestral crossing with an individual belonging to a coloured race at a period sufficiently remote for it to have been forgotten. In the present case the parents of the child had no knowledge of such an incident. The mother was dark-complexioned (*brune*), but not to an extreme degree; the father's hair was of a deep chestnut colour (*chatain foncé*); the infant was very dark-complexioned and had patches of black pigment on his ocular conjunctivæ. The mother said that an elder brother, now deceased, showed a similar mark.

Reform of Pharmaceutical Studies.

The Superior Council of Public Instruction has been considering the reform of the curriculum of pharmaceutical students. The studies necessary for the diploma extend over five years, of which the first is probationary and is spent in a [illegible] preliminary examination. During the four years of the regular course students must keep 16 quarterly terms, and pass three preliminary and three final examinations. The new regulations will come into force on Nov. 1st, 1910.

August 3rd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The National Congress of Internal Medicine.

WITH an organising committee (Comitato Ordinatore) composed of the Senators Camillo Golgi and Luigi Mangiagalli (honorary presidents), Dr. Luigi Devoto (acting president), Dr. Carlo Forlanini and Dr. Maroni (vice-presidents), Dr. A. Boni (general secretary), and a strong working staff, this Congress, the nineteenth in the series, will hold its sittings from Oct. 4th to 8th next in Milan under exceptionally favourable auspices. The programme is an interesting one alike for the themes to be reported on and discussed and for the experts who are engaged to lead off and to follow suit. The first on the list is the Present State of Study, Scientific and Clinical on Cancer (reporters, Professor Devoto, Professor Moreschi, and Professor Veratti); the second, New Horizons in the Pathology and Therapeutics of Nephritis (reporter [illegible] Calabrese); the third, [illegible] Professor Bozzolo and [illegible] Objective Review of Italian Discovery and Scientific Work (reporter, Professor Giuffrè) In addition to this, there will be a "conference," introduced by the Senator Professor Mangiagalli, on the Mechanical Factor and the Biological Factor in the Pathology of Pregnancy, followed by a practical demonstration entitled, "Röntgenological Investigation of the Digestive Tract," by Professor Gortan. The English-speaking colleague is always courteously welcomed and entertained at these congresses, at none more cordially than in the schools of the Alta Italia, where at Pavia, as at Padua and Turin, his compatriots have studied to such effective purpose in the past.

The Policlinico of the University of Pavia.

While on the subject of Upper Italy and its medical schools I may mention that the great Lombard seat of learning is about to add to its resources a Policlinico on the lines of its Roman sister, the plans for which, eight in number, are to be exhibited on Sunday next (August 1st) in the Aula Magna of the University before the technical committee organised *ad hoc* by the Rector, the Senator Professor Camillo Golgi. On this committee, composed of seven experts, [illegible] president [illegible] iversity of [illegible] ademy of Fine Art in the same city. The Policlinico, among its many functions, will fulfil that of instruction in every branch of the profession. Its site will be in one of the most attractive quarters of Pavia, of which it is designed to be at once a humanitarian institution and an artistic ornament. Its estimated cost is at present about 3,000,000 fr. (£120,000).

Musicotherapia.

"The hyperæsthesia of our overwrought civilisation," as it has been somewhat pompously designated, is evoking new, or adapting old, therapeutic remedies—among the latter, according to Dr. F. Stoduto in the *Medicina Italiana*, being that of music, which Plato theoretically, and the Father of Medicine clinically, recognised as part of the equipment of the healing art.

> "As martial music is to fighting men,
> Should song be to humanity,"

sings the Victorian poet, and there is no doubt that the first of these æsthetic resources, with its appeal to rhythm and harmony, has its salutary uses, whether to soldiers on the march or to the public in quest of recreation, mental as well as physical, in the concert room. Its extension to the treatment of the invalid, particularly in the weary hours of convalescence, is a not unnatural development of the same idea —empirically recognised by the great Napoleon when he ordered the band of the "Régiment d'Orient" to play under the windows of the hospital, as well as by the military authorities of France in the day now passing, from whom the regimental bands in the provinces have orders, once or twice a week, to perform in hearing of the invalid wards of the garrison. The eminent French alienists, Pinel and Esquirol, were fully alive to the efficacy of music in many cases of mental disease, melancholia particularly; Dr. Fodéré found in the same art a stimulant or a sedative, indicated in special forms of insanity; and another authority, Dr. Rocquas, attests its clinical value in hypochondria. Dr. Stodato has many other witnesses to tell us, or remind us, of in the same sense; while, in the normal subject, the exercise of the voice in singing or, as Celsus recommends, in elocution needs no vindication as an adjunct to the promotion of health. The subject, as handled by the Italian physician, is a fascinating one and will doubtless attract to its discussion many other experts who are votaries at once of Hygiea and Melpomene.

July 30th.

THE University of Vienna has just conferred the M.D. degree on a lady who had previously obtained the Doctorate of Philosophy. This is probably the first time that a lady has held the double doctorate in any European University. The lady in question is the Countess Albertina Fritzi Marschall.

pupils in the University, and when (after a long interval) Fraser obtained (by examination) the Fellowship of the Royal College of Surgeons in 1895 in the school of which he lectured, the council of that institution acted wisely and well in electing him to the examinership in anatomy—a position which he retained to the close of his life and to the satisfaction of all concerned; even the rejected candidate was hardly ever heard to insinuate that his merits had been unfairly rated. Fraser's personal power in the school was emphasised by his appointment as "Dean of the Schools of Surgery" in 1905. His energy and directive skill and tact were never exercised with better effect than in connection with the duties of that position, which he retained to the close of his life. His mental energy was equalled (and illustrated) only by his physical; during the whole time of his professoriate at the Irish College of Surgeons he was never known to be a day absent from illness until he was struck down by that which ended in his death. He contracted some septic poisoning during the process of injecting a body for dissecting-room purposes in the early part of the present year when the period of his 25 years' service had just been completed, in celebration of which occasion he was presented with a service of memorial plate by the council and professors of the College at their last annual dinner.

Professor Fraser was assiduously attended in his illness by Mr. William Taylor, and his school colleague, Professor A. H. White. Copious pleural effusion took place, and on one occasion 70 ounces of septic fluid were removed. As in cases of most men of the cast-iron type of constitution, he struggled hard against his illness at first, and some of his friends thought that his early return to his beloved work was the final cause which made the fatal issue inevitable. He returned to his native home in Scotland some three weeks before his death.

ANDREW JAMES DUNCAN, M.D. EDIN., L.R.C.S. EDIN.

Dr. Andrew J. Duncan of Nethergate House, Dundee, who died on July 7th, after an illness of ten days from cerebral hæmorrhage, was born in India, his father having been in the service of the Honourable East India Company. His grandfather was the Rev. Dr. Andrew Duncan of Ratho, a Moderator of the General Assembly of the Church of Scotland, and for a long time the principal clerk of that court. Dr. Duncan had a distinguished university career and graduated M.D. in 1865. After studying for a year in Paris and Vienna he settled in Dundee in 1866. He very soon acquired a large practice and took a leading place among his professional brethren. For many years he acted as secretary to the Forfarshire Medical Association, and the established position which this body now holds is due in no small measure to his efforts in furthering its objects at that early period of its existence. He had a lifelong connexion with the Dundee Royal Infirmary, and held successively the positions of physician, consulting physician, and director. He was also one of the surgeons of the Dundee Eye Institution. In all professional affairs he took a warm and active interest, and a few years ago he was elected, for the usual term, President of the local branch of the British Medical Association. He was an able and careful physician, a refined, genial, and upright man, and his memory will always be held in the deepest respect by all who knew him.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—On July 29th, Licences to practise, and Diplomas of Member, were respectively conferred upon the under-mentioned gentlemen, who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England, and who have complied with the necessary by-laws:—

Richard Bernard Abraham, St. Thomas's Hospital; Gerald Graham Alderson, B.A. Cantab., Cambridge University and University College Hospital; Frederick James Aldridge, B.A. Oxon., Oxford University and St. Thomas's Hospital; Emmanuel Caetan Alles, L.M. & S. Ceylon, Ceylon Medical College, King's College and Middlesex Hospitals; Edward Bruce Allnutt, St. Bartholomew's Hospital; Frederick Leigh Angior, L.S.A. Lond., Liverpool University; Charles William Archer, B.A. Cantab., Cambridge University and St Bartholomew's Hospital; William Reginald Ward Asplen, Westminster Hospital; Joseph Dudley Benjafield, University College Hospital; Rustom Hormasji Bharucha, L.M. & S. Bombay, Bombay University, King's College, and University College Hospitals; Thomas Knowles Boney, St. Bartholomew's Hospital; Juan Manuel Brito-Salazar, M.D. Caracas, Caracas University and Middlesex Hospital; Samuel Stanley Brook, Guy's Hospital; Arthur James Brown, London Hospital; Walter Holcroft Cam, B.A. Cantab., Cambridge University and London Hospital; Arthur Skelding Cane, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Richard Stocker Carey, B.A. Cantab., Cambridge University and London Hospital; William John Chambers, M.B. Toronto, Toronto University and Middlesex Hospital; Keshiv Sadashiva Chasker, Bombay University, University C [illegible] Harold Martin McC [illegible] Bartholomew's Hos [illegible] Hospital; Robert [illegible] John Westray Crop [illegible] pool University; [illegible] Cutler, Guy's Hospital; Richard Molesworth Dennys, St. Bartholomew's Hospital; Gopal Vinayak Deshmukh, L.M. & S. Bombay, Bombay University and London Hospital; Alan MacDonald Dick, M.B., B.S. Edin., Edinburgh University; Robert Sydney Doran, Charing Cross Hospital; Marc Antoine Emile Duvivier, Guy's Hospital; Reginald Fisher, B.A. Cantab., Cambridge University and St. George's Hospital; Robert Hankinson Williams Fisher, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Alexander Lindsay Fitzmaurice, Guy's Hospital; Percy Leslie Foote, Otago University and London Hospital; John Crofton Fox, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Arthur Gordon Valpy French, St. Thomas's Hospital; Stephen Gordon, [illegible] James Graves, Co [illegible] Hospitals; John [illegible] sity College, Bri [illegible] Reginald Harvey, Sheffield University and Guy's Hospital; Herbert Wilks Heasman, Guy's Hospital; Joseph Stanley Hopwood, St. Thomas's Hospital; Arthur H [illegible] Charing Cross Hospital; David Isaacs, Guy's [illegible] London Hospital; Geoffrey [illegible] Thomas James Johnston, M. [illegible] London Hospital; David Ker [illegible] Martyn Henry Langford, Middlesex Hospital; William [illegible] M.A. Cantab., Cambridge University and Guy's Hospital; Ronald John Barcham Leney, B.A. Cantab., Cambridge University and London Hospital; John Thomas Lloyd, London Hospital; Hugh McLean, B.A. Cantab., Cambridge University and London Hospital; Russell Hardy Sidney Marshall, St. Mary's Hospital; Bernard Constable Maybury, St. Thomas's Hospital; Ernest Mayer, M.D. Zurich, Zurich University and St. Bartholomew's Hospital; Charles Anderson Meaden, St. Bartholomew's Hospital; John Cecil Wilson Methven, London Hospital; John Allen Noble, B.A. Oxon, Oxford [illegible] Hospital; Philip Douglas Oakley, [illegible] nich, Munich University and [illegible] inson, Otago University and [illegible] d Parsons, St. Mary's Hospital; Frederick Charles Pridham, St. Thomas's Hospital; William [illegible] Cardiff and London Hospital; Reginald George [illegible] Joseph Xavier Robert, M.B. [illegible] Hospital, and Birmingham [illegible] Ryland, St. Bartholomew's Hos [illegible] St. Thomas's and London Hosp [illegible] Charing Cross Hospital; Herbert [illegible] Hospital; *William John Smith, [illegible] and London Hospital; Walter [illegible] Charing Cross Hospital; Cecil C [illegible] Bertram Alfred Wood Stone, B. [illegible] University College, Bristol; Wil [illegible] Cantab., Cambridge University [illegible] Ariaratnapillai Vairakiam, L.M. & [illegible] and London Hospital; Johann [illegible] and John Murray Weddell, B.A [illegible] and St. Bartholomew's Hospital, [illegible] King's College Hospital; David Phillips Williams, Charing Cross Hospital; Stanislaus Swonnell Morton Wood, Westminster Hospital; and Charles Reynolds Woodruff, St. Bartholomew's Hospital.

* Diploma of M.R.C.S. granted on June 10th.

Diplomas in Public Health have been conferred upon the following gentlemen:—

Andrew Allison, M.B., Ch.B. Glasg., Glasgow University; Hugh Barr, M.B., Ch.B. Glasg., Glasgow University and King's College; James Aylmer Beamish, M.B., B.Ch. R.U.I., Royal University of Ireland and University College; Harry Boulcott Bolus, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and Guy's Hospital; Clement Henry Burton Bradley, M.B., Ch.M. Syd., L.R.C.P., M.R.C.S., Sydney University and University College; Thomas Evans, M.B. Lond., University College; James Fairley, M.B., Ch.B. Glasg., Glasgow University and University College; Robert Mylcraine Freer, M.D., C.M. Edin., Edinburgh University and London Hospital; Walter Ernest Fry, L.R.C.P., M.R.C.S., London Hospital and University College; Henry William Harding, M.D. Lond., L.R.C.P., M.R.C.S., St [illegible] London Hospitals; Richard Athelstane Parker [illegible] M.R.C.S., Cambridge University and [illegible] Thomas Edward Holmes, M.D., B [illegible] versity, Guy's Hospital, and Univers [illegible] Edward Littledale, M.D., B.Ch. Dub., Dublin University and [illegible] versity College; Walter St. Clare McClure, L.R.C.P., M.R.C.S., Sheffield University, London Hospital, and University College; Krishnaji Shripat Mhaskar, M.D., L.M. & S. Bombay, Bombay University and University College; Richard Alfred O'Brien, M.D., B.S. Melb., Melbourne University and University College; and Percy William Spaull, L.R.C.P., M.R.C.S., St. Thomas's Hospital and King's College.

The Diploma of M.R.C.S. has been granted, under the old regulations, to the under-mentioned gentleman:—

William James Morton, M.D., M.B., C.M. Aberd., L.R.C.P. & S. Edin., Edinburgh and Aberdeen Universities.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery held on July 19th, 22nd, and 23rd, the following gentlemen were approved in the subjects indicated below:—

Chemistry and Physics.—William Adderley, Brighton Technical [illegible] ...ical Technical College; ...ollege, Bristol; Robert ...laude Frederick Haine, ...ford, University College, ...ic Institute; Douglas ...echnical College; Arthur ...homas Eric Henderson, [illegible] Preston; [illegible] Wilmer [illegible]

C[illegible]

P[illegible]

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidate has passed the primary part of the Fellowship examination:—

J. B. Dorli, L.M. & S., Bombay University.

The following candidates have passed the final part of the Fellowship examination and have been admitted Fellows:—

J. Gordon, L.R.C.S.I.; L. S. Machado, L.R.C.S. Edin.; T. Murphy, B.Ch. Melbourne University; and F. Spicer, M.R.C.S. Eng.

APOTHECARIES' HALL OF IRELAND.—At the recent quarterly examinations the following candidates were successful:—

[illegible] and [illegible] ...erry, [illegible] and *James Stuart.*

THE WEST AFRICAN MEDICAL STAFF.—The following retirements are announced:—Mr. A. R. Rendle, medical officer, Southern Nigeria (Feb. 12th); Mr. J. C. Ryan, medical officer, Southern Nigeria (with gratuity, May 31st); Mr. R. E. McConnell, medical officer, Gold Coast (July 2nd); Mr. J. B. H. Davson, senior medical officer, Gold Coast (on pension, July 26th); and Mr. G. L Barker, medical officer, Gold Coast (receiving a gratuity, August 25th).—Mr. J. Tichborne, late senior medical officer, Northern Nigeria, has been reappointed senior medical officer, Gold Coast, vice Mr. J. B H. Davson, retired —The following have been appointed to the staff:—Dr. O. G. F. Luhn (Southern Nigeria, Feb. 20th), Dr. E. Slack (Gold Coast, March 6th), Dr. H. B Kent (Southern Nigeria, April 3rd), Mr. A. W. H. [illegible] Mr. E. M. Franklin (Sou[illegible] Brabazon (Gold Coast, J[illegible] (Southern Nigeria, July 24th). All dates refer to the present year.

KING EDWARD'S HOSPITAL FUND AND CHARITY ENTERTAINMENTS.—A subcommittee of King Edward's Hospital Fund for London, consisting of Lord Cavendish, Mr. J. G. Griffiths, Mr. A. E. Sydney, and Mr. F. M. Fry, were appointed in May last by the executive committee of King Edward's Hospital Fund to consider what action, if any, it might be advisable for the Fund to take in reference to the question of the expenses of charity entertainments. This committee has now issued its report, which states (1) that charity entertainments have been found to be a *means of securing income which could not be obtained in any other way*; (2) that neither extravagance nor abuse prevails to any large or general extent; and (3) that there are some points which require consideration by hospital authorities as soon as the proposal for an entertainment is mooted. If the hospital itself is responsible [illegible] management of an entertainment the question of the [illegible] between expenses and receipts should be fully con[illegible] On the other hand, in the case of entertainments [illegible]d by outside agencies a hospital does not incur the [illegible]nancial risk. Reference is made to the cost of the [illegible] of *professional* artists. The report adds: "The extent to which members of the dramatic, musical, and kindred professions give their time and skill gratuitously and ungrudgingly to the assistance of charity is a matter of common knowledge. ...... But ...... it is occasionally necessary for hospital committees to see that the deservedly high reputation of the professions in this respect is not used by less scrupulous or less public-spirited persons as a cloak for individual profit." In conclusion, the subcommittee states that it does not propose to formulate regulations binding upon hospitals, but it thinks that a perusal of its report may assist the managing committees in framing rules for their own protection.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Poor-law Medical Officers in Scotland.

On the motion of Mr. CATHCART WASON a return has been ordered by the House of Commons showing in how many and what parishes during the past three years Poor law medical officers in Scotland have vacated office, and what period in each case has elapsed before the appointments have been permanently refilled.

Milk and Dairies (Scotland) Bill.

The Milk and Dairies (Scotland) Bill has passed its report stage in the House of Lords with a few alterations in the text. An amendment has been introduced into the Bill in consequence of the changes made in it in committee to lay down that the local authority may refuse to grant a certificate of registration to dairy premises, or may revoke it if the premises are, or become, unsuitable for the purpose of a dairy business.

The Ambulance Service in the Metropolis.

Mr. PEEL has introduced a Bill into the House of Commons "to enable the managers of the Metropolitan Asylum District to establish and maintain an ambulance service in the county of London, and to empower the Commissioner of Police of the metropolis to enter into agreements with the said managers and with guardians of the poor with respect to the use and working of ambulances" The Bill was read a first time. Another Bill dealing with metropolitan ambulances is at present before a Select Committee of the House of Commons.

The Coroners Committee.

The first report of the Departmental Committee appointed to inquire into the law relating to coroners and coroners' inquests and into the practice in coroners' courts is a short document of an interim character, and embodying no definite conclusions. It states that the Committee has held 17 meetings and examined 32 witnesses with regard to matters specified in the terms of reference and also with regard to the question of deaths resulting from the administration of anæsthetics and the question of the danger arising from the use of flannelette in articles of clothing. Further evidence will be taken by the committee in the immediate future, but it is considered desirable that what has already been heard should be made public. It is issued in a separate blue book.

Milk Legislation.

The prospect of legislation relating to milk-supplies reaching the Statute Book this session becomes more remote. The fact is that a good deal of concern for the progress of both the Scottish and English Milk Bills is beginning to be felt by Members of Parliament who are interested in them. The question of compensation for cows slaughtered as tuberculous under the Tuberculosis Order of the Board of Agriculture presents difficulties which it may take time to overcome and in the pressure of other business, milk legislation may be sacrificed.

HOUSE OF COMMONS.

THURSDAY, JULY 29TH.

Bacteriological Investigations at Khartoum.

Sir HENRY CRAIK asked the Secretary of State for Foreign Affairs whether, in view of the useful work of the Gordon College at Khar-[illegible]

SPLENDIDE MENDAX.

THE following story affords an awful warning to those medical golfers whose inveterate addiction to their sport may lead them to diverge from their habitual accuracy of statement, and to all others who may be tempted to formulate an excuse without well considering its "unities." There was a certain surgeon hailing from this side of St. George's Channel and enjoying the hospitality of a Belfast house during the meeting of the British Medical Association. After his strenuous scientific exertions on the Thursday morning of the meeting, he betook himself to the links at Newcastle, a train journey which separated him by well over an hour from Belfast. How he fared on the links has not come to our ears, for the story reaches its climax in the city, at his hostess's dinner-table, where he had failed to put in an appearance. After allowing her absent guest the customary amount of grace, she had marshalled her dinner ranks and was proceeding with the meal. With the fish arrived a telegram from the absent one, in some such terms as this: "Very sorry. Missed train. Forgot to alter watch from English to Irish time." The message was communicated to the company, and as the proper murmur of sympathy was arising for the poor dinnerless fellow stranded at a distant railway station, his hostess suddenly exclaimed: "Hardly adequate! That would have made him just 25 minutes too early."

CONTRIBUTIONS TO THE HARRIS FUND.

AN appeal on behalf of the family of the late Mr. C. E. Harris, Ph.D., was published in THE LANCET of July 17th, p. 187. The following contributions have been received to date and are herewith gratefully acknowledged:—

Part of the proceeds of this Fund will serve to defray the most pressing needs of the family, and the remainder will be invested in a ten years' annuity for the widow, it being hoped that after that time the children will be in a position to support their mother. Further contributions are earnestly requested and may be sent to N. H. Turner, L.R.C.P., M.R.C.S., &c., 35, Highbury-grove, London, N.; or Carl Prausnitz, M.D., "Normanton," Grove-road, Sutton, Surrey.

LUTTERWORTH GUARDIANS AND A HINDU MEDICAL OFFICER.

THE Lutterworth (Leicestershire) board of guardians recently appointed Mr. J. C. Bhuttercharji, a native of India, as medical officer for the third and fourth districts. At their meeting on July 29th the Local Government Board wrote enclosing the following petition which had been sent to it and asking for the guardians' observations on the matter:—

> "We, the undersigned pauper patients of the third and fourth districts of the Lutterworth Union, humbly petition the Local Government Board that the recent action of the Lutterworth guardians in appointing Dr. J. C. Bhuttercharji, a native of India, be set aside, and that we, who are unable to choose our own doctor, may be given one of our own race and colour."

Then followed 20 signatures. Mr. L. T. Topham said that on hearing of the petition, and in order to save the time of the board, he had asked the relieving officer how the poor people liked the doctor, and his report was almost unanimously in his favour. The Rev. C. G. Squirrell moved "that the board reaffirms its confidence in Dr. Bhuttercharji, and regrets the unfair treatment he is now receiving." Mr. S. A. Johnson seconded, and it was unanimously agreed to. In the subsequent discussion it was suggested that the signatures to the petition had not been obtained in a proper manner. Finally, the guardians interviewed Mr. Bhuttercharji and informed him that they had unanimously reaffirmed their confidence in him and hoped the Local Government Board would sanction his appointment.

THE POSSESSION OF FIREARMS.

AT the Hastings Quarter Sessions on July 27th Rene de Bourbon appealed against a conviction by the magistrates for having in his possession loaded firearms while in a state of intoxication. The decision of the magistrates was a term of imprisonment, and the deputy Recorder, Mr. George Elliott, K.C., after hearing counsel for the police and for the appellant, varied the sentence to one of the maximum penalty, the appellant agreeing to pay all the costs incurred and to be bound over. This decision was given on the understanding that the appellant was leaving the country for the Argentine, and the deputy Recorder expressed the hope that he would keep his promise not to come back to England. Bourbon had on several previous occasions been before the Hastings justices, and once before a pistol was found upon him. Recent events have shown that the Government has good ground for reviewing the law as it stands to-day as regards the sale of firearms. Something should be done to check the indiscriminate sale of these highly dangerous weapons.

FRENCH DICTIONARIES.

To the Editor of THE LANCET.

SIR,—I am much obliged to Dr. A. Cordes for his reply in THE LANCET of July 17th and have obtained the small dictionary which he indicated. I find that the full title of it is "Petit Dictionnaire National, Par Bescherelle Aîné, Auteur du Grand Dictionnaire National Paris Garnier frères, Éditeurs, 6, Rue des Saints-Pères." Messrs. Hachette et Cie, Charing Cross, London, were kind enough to procure it for me The price is 2*s*. The number of pages is 541. I am also obliged for the information about Bellows's dictionary, which I have known for many years. Thanking you for allowing me some of your valuable space,

I am, Sir, yours faithfully,

London, July 27th, 1909. GUILLAUME.

◆

H. R. K.—Dr. Julius Hirschberg's work on "The Renaissance of Ophthalmology" has been translated from the German into French by Dr. Daniel van Duyse, Professor of Ophthalmology in the University of Ghent, and it was the French translation which was reviewed in THE LANCET of June 19th last, p. 1759. This French translation is to be obtained from Wilhelm Engelmann, Leipzig. We do not know of an English translation of the work.

G. J. B.—Radium applicators similar to those used by Dr. Louis Wickham *can be obtained from* M. Henri Farjas, 15, *Rue Vignon*, Paris, and a letter written to him will procure all the necessary information and an illustrated catalogue.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1909, which was completed with the issue of June 26th, and the Title-page to the volume, were given in THE LANCET of July 3rd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

The Hunterian Lectures

ON

MALFORMATIONS OF THE HEART.

Delivered before the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1909,

By ARTHUR KEITH, M.D. Aberd., F.R.C.S. Eng.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND CONSERVATOR OF THE MUSEUM

LECTURE II.[1]

Delivered on March 10th

Transposition of the arterial stems.—If the theory of a bulbus element in the human heart helps us to understand the numerous abnormalities which were discussed in my last lecture, it is of even greater assistance in clearing up the various abnormal and very puzzling conditions included under the term of transposition of the aorta and pulmonary artery. The pulmonary artery in these cases of transposition arises behind the aorta, over the left ventricle, while the aorta springs from the infundibulum of the right ventricle. Thus the venous blood is thrown by the right side of the heart into the aorta and systemic circulation while the arterial blood is carried back to the lungs by the pulmonary artery. Altogether I have examined 25 hearts in which the arterial trunks were transposed, six of them being in the College collection Fig. 11 shows the arrangement of parts in a specimen which may be regarded as typical of the group. The aorta, recognised not only by its distribution but also by the fact that the coronary arteries are given off from it, arises from the infundibulum of the right ventricle—that part of the ventricle which is derived from the bulbus cordis. The pulmonary artery occupies the position of the aorta and springs from the left ventricle. The exact condition of parts is best seen by examining a section made at the base of the heart (Fig. 12). *In the normal heart the aortic orifice is situated behind the* pulmonary orifice and immediately anterior to the left auricle and left auriculo ventricular orifice. The aortic cusps corresponding to the origin of the right and left coronary arteries—right and left coronary cusps—are situated towards the sternal margin of the aorta, the non-coronary towards the dorsal margin. In the abnormal heart the position of parts is reversed; now the aorta is in front and the pulmonary artery behind; the position of the aortic cusps is reversed, the non-coronary cusps being now not on the dorsal but on the sternal margin of the aorta. Further, it is to be noted that the aorta arises from the infundibulum or persistent bulbus cordis, while the pulmonary artery arises directly from the left ventricle, the part of the bulbus corresponding to it having atropied, but the atrophy is sometimes only partial.

FIGS 11 AND 12.

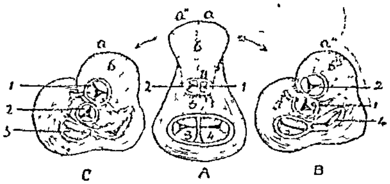
Fig 11—Heart showing transposition of the great stems (viewed on its right side). 1, Aorta; 2, pulmonary artery arising behind aorta, 3, right auricle, 4, superior vena cava, and 5, infundibulum of right ventricle giving origin to aorta

Fig. 12—The base of the heart shown in Fig 11. 1, Pulmonary artery, 2, aorta (non coronary cusp), 3, anterior cusp of mitral valve, 4, septal cusp of tricuspid, 5, infundibulum of right ventricle, and 6, triangle of persistent basal musculature

How is transposition brought about? The explanation offered by Rokitansky—the only explanation yet given—is that the aortic end of the heart may undergo an abnormal degree of rotation, either to the right hand or to the left, and the form of transposition depends on the extent of the rotation. Such a theory does not really help us The clue to the problem is to be found in a study of the remarkable transformation of the mammalian embryonic heart. We have already seen how the lesser curvature of the bulbo-ventricular segment of the cardiac tube shrivels up during the early period of development. By the third week the ventricular segment of the primitive cardiac tube is bent transversely towards the right (Fig. 9, Lecture I.), so that it occupies a position comparable to the adult stomach, the *auricular canal representing the œsophagus and the bulbar* part the pyloric end In Fig. 13 A I have represented what I conceive to be the primitive form of the bulbo-ventricular part of the heart; in Fig 13 B is shown the atrophy that leads to the aorta being brought into juxtaposition with the mitral orifice; and in 13 C the changes which lead to the pulmonary artery being brought into contact with that orifice. In the first case the bulbus connected with the aorta atrophies and the part connected with the pulmonary artery undergoes an expansion; in the second case the processes are reversed. The aorta instead of being the dorsal vessel is now the ventral and situated towards the greater instead of towards the lesser curvature (Fig 13 C). With the atrophy of the lesser curvature of the ventricle and pulmonary part of the bulbus, it is the pulmonary artery in place of the aorta that comes into contact with the auricles In effect, the origin of the great vessels is reversed as regards the auricular canal (compare 13 B with 13 C). No one has seen an embryo in which the pulmonary part of the bulbus was undergoing a process of atrophy in place of one of expansion, but the assumption is justified by the fact that a complete explanation is thereby obtained of the condition seen in hearts with transposed arterial trunks. The theory explains why the aorta is in front of the pulmonary artery and also the reversion in the position of its valves We see further why the bulbus cordis persists in connexion with the aorta and forms the infundibulum, while the part of the bulbus connected with the pulmonary artery atrophies

FIG. 13.



Showing the atrophy of the primitive cardiac tube which leads to the normal position of the arterial orifices (B) and to the abnormal position (C) A, Primitive ventricle and bulbus cordis viewed on the aspect of their lesser curvature B, The normal position of the arterial orifices C, The abnormal position [illegible] orifice, 3, mitral orifice, [illegible] common ventricle, and 6, [illegible] f bulbus which atrophies [illegible] half of bulbus which atrophies in C, the abnormal form.

ON THE PREPARATION AND KEEPING PROPERTIES OF ANTITYPHOID VACCINES.

By D. SEMPLE, M.D., M.CH. R.U.I., D.P.H. CAMB.,
LIEUTENANT-COLONEL, R.A.M.C. (RETIRED); DIRECTOR, CENTRAL RESEARCH INSTITUTE, KASAULI, PUNJAB, INDIA;
AND
H. S. MATSON, M.B., B.S. LOND.,
CAPTAIN, I.M.S.

THE use of bacterial vaccines for therapeutic and prophylactic purposes is still sufficiently recent to allow of some divergence of opinion in the details of their preparation, and as this is a point which seriously affects their efficiency and keeping properties, the subject is worthy of consideration. In most laboratories where the preparation of bacterial vaccines is carried out it is the usual custom to sterilise by means of heat, and subsequently to add a small percentage of some reliable antiseptic such as carbolic acid or lysol.

A killed bacterial culture capable of functioning as a vaccine is in reality a toxin (chiefly endotoxin) and is composed of dead bacterial cells, together with their products of secretion and disintegration. According to Ehrlich, a toxin possesses two specific atomic groups—viz., a haptophore or combining group, and a toxophore or toxic group. The haptophore group when untampered with is known to be fairly stable, but it is very susceptible to the action of heat and certain chemical agents. A toxin of bacterial origin deprived of its haptophore group is no longer in a position to function as a toxin when used on susceptible animals, or to influence the cells of the body in such a way as to call forth an immunising response by the production of antibodies. Similarly, a bacterial vaccine deprived of its haptophore group, or which has been prepared in such a manner that the haptophore group becomes attenuated soon after preparation and finally disappears, is no longer to be relied upon in the production of an immunising response.

The toxophore group is more complicated than the haptophore group and is liable, even when untampered with, to become converted into toxoids, and in the case of the endotoxins into toxons; but even toxoids and toxons, provided their haptophore groups remain intact, are still capable of producing an active immunising response. Most of the bacterial vaccines with which we are acquainted are very sensitive to the action of heat, light, and also to some chemical substances. All are injuriously affected by oxidising agents and by strong bases and acids.

As very little is known about the chemical nature of the toxins which enter into the composition of vaccines, it follows that we are still in the dark as to the changes which take place when they are subjected to the action of heat, light, and chemical agents. There are, however, a few facts which have gradually come to be recognised, and in dealing with toxins and vaccines it is necessary to take these facts into consideration.

The German Plague Commission, working in Bombay in 1898, proved that heating a vaccine to 60° C. after the addition of an antiseptic greatly diminishes its immunising properties, and may remove them altogether. Oppenheim and Mitchell[1] make the following statement about the action of heat on toxins: "A special characteristic of toxins is their extreme sensitiveness to the action of heat. In their normal solutions they soon perish at temperatures above 50° C. At 80° C. their action is at once destroyed, and even at 45° C. they are slowly decomposed; individual ferments differ but little in this respect. On the other hand, they offer great resistance to the action of dry heat. Solid preparations can be heated to over 100° C. without suffering injury."

One of us (H. S. M.) has found that evaporation at 60° C. from an alcoholic solution completely destroyed the toxic properties of a filtrate of a broth culture of Shiga's dysentery bacillus, of which a small dose (5 cubic centimetres) had previously proved rapidly fatal to a rabbit. Kitasato in 1891 proved that diphtheria and tetanus poisons in solution are rapidly destroyed by the action of sunlight and diffuse daylight. In the dry state we know that these poisons can withstand the action of light for a prolonged period. It is a well-known fact that the specific agglutinating reaction of a serum can take place when dead bacteria are used, but when the bacteria have been killed by heating the emulsions or cultures to a temperature of 60° C. or more, their agglutinability is diminished, and more agglutinins are required to produce the specific reaction.

The chemical agents harmful to toxins are numerous. It would appear that toxins are very sensitive to nearly all chemical agents, with the exception of carbolic acid. Iodine is an example of a substance which acts on the toxophore group of toxins to form toxoids. Advantage is taken of this fact in the early stages of the immunisation of animals with tetanus toxin. A small percentage of iodine mixed with the toxin during the first few doses tones down its toxicity and paves the way for the administration of the untreated toxin.

It is evident from the foregoing facts that the utmost care should be taken in the preparation of a vaccine intended for therapeutic or prophylactic purposes, to avoid any conditions known to lead to the disintegration of the active principle. It is necessary that its original properties should be interfered with as little as possible.

With the exception of anthrax vaccine, bacterial vaccines are prepared from non-spore-forming bacteria (strictly speaking, anthrax is only a modified exception, for the vaccines in this case are generally prepared from cultures in which spore formation is artificially prevented, or before it has had time to take place). This fact alone renders the sterilisation of a vaccine a comparatively easy task, provided that care is taken to ensure that absolutely pure cultures and pure media are used.

The bacillus typhosus is killed by heating it either in a broth medium or in normal salt solution for a few minutes at a temperature of from 57° to 60° C. It is also killed in either of the above media within 24 hours by the addition of 0·5 per cent. pure carbolic acid. In the preparation of antityphoid vaccine it is necessary to kill the living cultures of B. typhosus from which it is prepared, and it is necessary also to lessen the chances of any subsequent contamination being able to take place. Heating the vaccine at a temperature of 60° C. for 20 minutes, or 53° C. for one hour, will accomplish the former, and the addition of 0·5 per cent. carbolic acid, or 0·25 per cent. lysol, the latter. The addition of 0·5 per cent. pure carbolic acid is by itself quite sufficient to accomplish both objects, and besides it has the additional advantage of enabling us to dispense with the harmful effects of heat.

Another essential in the preparation of vaccines is to prepare them in such a way that they retain their immunising properties as long as possible. With the object of testing whether a vaccine sterilised by the addition of 0·5 per cent. carbolic acid and without any preliminary heating process retains its immunising properties for more than a year, we carried out the series of experiments recorded in this paper, and tested a vaccine stored at room temperature in a dark cupboard at the Central Research Institute, Kasauli, for over two years, against a freshly prepared vaccine. Both vaccines were prepared from the same strain of B. typhosus and in exactly the same way—viz., from a broth culture incubated at 37° C. for 48 hours and then sterilised by the addition of 0·5 per cent. carbolic acid only. The results of the experiments carried out on rabbits and guinea-pigs with these two vaccines (old and fresh vaccines) are recorded in the tables numbered I. to VII. inclusive and Charts 1 and 2. The blood change which took place when the same two vaccines were used on men are recorded in Tables VIII. and IX. and Charts 3 and 4.

In the tables numbered X. to XIII. inclusive, and Charts 5, 6, and 7, three vaccines, each prepared from the same strain of B. typhosus as that used in the previous experiments, but sterilised by heat and the subsequent addition of an antiseptic, are contrasted—viz., an old vaccine and a fresh vaccine, each sterilised by heating at a temperature of 60° C. for 20 minutes, and the subsequent addition of 0·5 per cent. carbolic acid; and a fresh vaccine sterilised by heating for one hour at a temperature of 53° C. and the subsequent addition of 0·25 per cent. lysol.

The results recorded in these tables and the charts attached to them require little or no explanation. As regards the blood changes which took place after inoculation with these vaccines, it was decided to test only for the agglutination and opsonic reactions. In testing for opsonins the

serum was pooled (with the exception of the experiments recorded in Tables I. and XIII., where only one animal was used) and diluted 1 in 5, then filled into glass pipettes and heated in a water bath for 15 minutes at a temperature of 58° C. We found that more accurate estimations could be obtained by using the serum diluted to this extent than by using an undiluted serum. Two volumes of the diluted and heated serum were added to 2 volumes of washed corpuscles and 1 volume of B. typhosus emulsion, then carefully mixed and filled into glass pipettes and incubated at 37° C. for 15 minutes. When taken out of the incubator the contents of the pipettes were again mixed and films prepared and stained in the usual way, and 50 polymorphonuclear corpuscles were counted. In addition to these blood tests, the rabbits and guinea-pigs inoculated were subjected to a

[illegible]

hours. Of this culture 5 cubic centimetres given intraperitoneally killed the control rabbits in 12 hours, and 0·75 cubic centimetre the control guinea-pigs in from 12 to 14

[illegible] immunised with the [illegible] addition of 0·5 per [illegible] of heat were able to survive one and a half lethal doses of the test typhoid culture given intraperitoneally without showing any apparent symptoms, but that none of them were able to withstand two lethal doses.

On reference to the opsonic and agglutination tables numbered I. to VII. (inclusive) and Charts 1 and 2 it will be seen that the opsonins and agglutinins are increased to practically the same extent whether we use a vaccine over two years old or a vaccine freshly prepared, provided that in both cases sterilisation has been carried out by means of carbolic acid only.

It is evident from these results and also from the results recorded in the Tables numbered VIII. and IX. and Charts 3 and 4 that an antityphoid vaccine sterilised by the addition of 0·5 per cent. carbolic acid and without any previous heating retains its immunising properties unimpaired for a period of two years at least In the Tables numbered X, XI., XII., and Charts 5 and 6, where a comparison is drawn between old and freshly prepared vaccines sterilised by means of a double process, viz., heating to 60° C. for 20 minutes, and the subsequent addition of 0·5 per cent. carbolic acid, it will be seen that the heated and carbolised vaccine has lost considerably in its immunising properties after two years, but that a fresh vaccine similarly prepared, although evidently efficient in producing a high degree of immunity, is not quite so efficient as an unheated vaccine.

Table XIII. and its accompanying chart (No. 7) demonstrate that a vaccine sterilised by heating for one hour at a temperature of 53° C., and the subsequent addition of 0·25 per cent. lysol (Leishman's method), produces a slightly higher response (as judged by the blood changes, but not by the effects of lethal doses) than a freshly prepared vaccine sterilised by heating for 20 minutes at 60° C., and the subsequent addition of 0·5 per cent. carbolic acid. Leishman,[2] however, states that the keeping properties of a vaccine prepared by this method cannot be relied upon for longer than three months. We are unable for the present to make any experiments on this point on account of not having an old vaccine sterilised by this method.

None of the rabbits immunised with a heated vaccine were able to survive the intraperitoneal inoculation of one and a half lethal doses of the test typhoid culture, but those

[2] Leishman, Harrison Grattan, Webb, and Kennedy: Journal of the R.A.M.C., October, 1908.

immunised with a freshly prepared heated vaccine survived one lethal dose When an old heated vaccine was used one lethal dose of the test culture proved fatal in one case but not in a second animal similarly immunised

It would appear from these experiments that sterilising a vaccine by means of heat diminishes its immunising properties, even though the vaccine be used when quite fresh, and it would also appear that heat has a marked effect in curtailing its keeping properties On the other hand, when sterilisation is carried out by adding 0 5 per cent carbolic acid only, no harmful effects are produced, and the vaccine retains its properties unimpaired for two years at least

It may be mentioned that one of us (D S) has prepared and used a staphylococcus vaccine, sterilised by the addition of 0·5 per cent. carbolic acid only, and with results in every way satisfactory. In dispensing with the aid of heat in sterilising a staphylococcus vaccine it would be safer to allow 48 hours to elapse before testing for sterility. Experience has proved that some strains of staphylococci resist 0·5 per cent carbolic acid longer than typhoid bacilli The principle here enunciated would apply to all bacterial vaccines now in use In the case of vaccines prepared from bacteria associated [illegible]
cases of st[illegible]
increased [illegible]
harmful effects either to the patient or the vaccine, but as a matter of fact considerably less than 1 per cent. would suffice

Conclusions

I The sterilisation of antityphoid vaccine can be efficiently accomplished by the addition of 0·5 per cent. carbolic acid

II Heating a vaccine in order to sterilise it introduces a harmful and unnecessary element which acts in two ways: (1) it diminishes its immunising properties, and (2) it curtails its keeping properties In the experiments here recorded the [illegible]
[illegible] tion of
[illegible] operties
[illegible] by the

fact that animals and men treated with a two years old vaccine prepared by this method show the same blood changes as those treated with a fresh vaccine similarly prepared; and (2) by the fact that animals treated with a two years old vaccine prepared by this method withstand the same amount of a virulent typhoid culture when given intraperitoneally as those treated with a fresh vaccine similarly prepared.

IV. Animals inoculated with antityphoid vaccine sterilised by the addition of 0·5 per cent. carbolic acid attain a higher degree of immunity (as proved by blood changes and the resistance to lethal doses of a virulent typhoid culture) than similar animals inoculated with a vaccine sterilised by heat (60° C. for 20 minutes, or 53° C. for one hour) and the subsequent addition of an antiseptic (carbolic acid 0·5 per cent., or lysol 0·25 per cent.).

V. An antityphoid vaccine sterilised by heating for 20 minutes at a temperature of 60° C., and the subsequent addition of 0·5 per cent. carbolic acid has considerably deteriorated after being kept for two years, as proved by the blood changes, and effects of lethal doses of a virulent typhoid culture in animals inoculated with this vaccine.

VI. Pure carbolic acid to the extent of 0·5 per cent. appears to us to be the best agent with which to sterilise bacterial vaccines, and its general adoption would obviate any necessity for heating.

CONGENITAL, HEREDITARY, AND FAMILY HÆMATURIA.

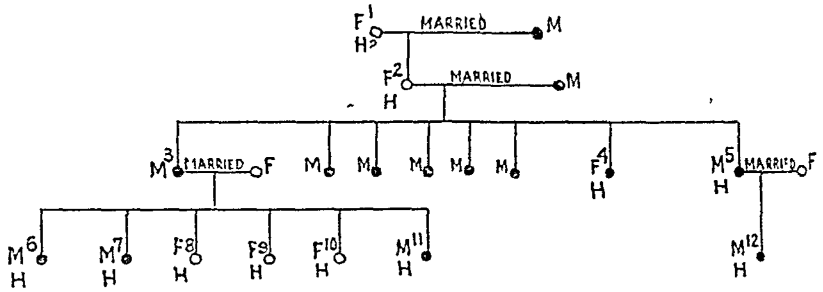
By JOHN AITKEN, M.D., CH.B. GLASG.,
ASSISTANT PHYSICIAN, KILMARNOCK INFIRMARY.

HEREDITARY hæmaturia appears to be a very rare condition. It was first described by Guthrie[1] in 1902 in a paper entitled "'Idiopathic,' or Congenital, Hereditary and Family Hæmaturia," in which he reported its occurrence in 12 members of one family. I have not been able to find any other reference to it in the literature. Atlee,[2] however, has reported "Three Cases of Recurrent Hæmaturia in One Family," which resemble very closely the cases under consideration, but in which there is no hereditary or congenital history.

The seven cases which are reported below are of one family which has been under my observation during the past seven years. So far as the history goes, the family is comprised in all of 17 persons, of whom 10 have suffered from hæmaturia. Testimony is conflicting as to whether the great-grandmother (No. 1 in the accompanying chart) had hæmaturia or not. She died at an advanced age from "senile decay" with dropsy. The great-grandfather was healthy. Their only child, a daughter (No. 2), had hæmaturia (according to the relatives), married, and had eight children (seven sons and one daughter), and died, aged 38 years, from "Addison's disease." Four of her sons died in infancy from an unknown cause; and one, aged 14 years, from an indefinite "brain trouble." There is no evidence of any of those having suffered from hæmaturia. The remaining three are alive. The eldest son, aged 31 years (No. 3), has not had hæmaturia, but his six children have all been hæmaturic; the second son (No. 5), aged 28 years, has suffered from hæmaturia, and his only child, aged 2 years, is also hæmaturic; and the daughter, aged 23 years (No. 4), unmarried, has hæmaturia. There is no history of hæmophilia, nor is there any rheumatic tendency in the family.

It is interesting to note that in this family the hæmaturia has been inherited, first, through the female side, and then on two occasions through the male side, in one case the transmitting male not being affected. In Guthrie's family inheritance was only through the females; and in Atlee's cases, though there is no reference to heredity, it is noted that the father died from uræmia.

The cases which have been under my observation are the granddaughter (No. 4) and the grandson's (No. 3) six children—i.e., the second and third affected generations. Four of the children, aged respectively 9, 5½, and 3½ years, and 11 months, are alive, and two are dead, one having died, aged 3 years, from acute nephritis with uræmia, and one aged 10 days, from broncho-pneumonia. All have suffered from hæmaturia. Their father is a strong healthy man, who has never had any illness, and the mother has had good health except for a transient hemiplegia following phlegmasia after childbirth. The following chart shows the relationships:—



H = Suffered from hæmaturia.

Guthrie based the diagnosis of his cases on the following points: the personal and family history, the occurrence of febrile exacerbations in which the hæmaturia far exceeds that of acute nephritis, the absence of œdema or dropsy and cardio-vascular changes, and the absence of all the well-known causes of hæmaturia, and my cases agree very closely with his description.

In all the six children the condition has probably been congenital. Two of them were noticed to pass blood-coloured urine during the first week of life; in three, blood was first observed at from 12 to 18 months, when the napkins were dispensed with; and in the sixth (aged 11 months), though to the eye the urine had a normal appearance, albumin was present and blood corpuscles microscopically in the first specimen obtained (at four months). In practically all the examinations I have made of these urines over a number of years blood has been present, usually giving the urine either a faint "smoky" or light red colour, with albumin often in excess of the blood. The children are also, with one exception, all subject to periodic febrile attacks occurring at irregular intervals, during which the quantity of blood passed is much increased. These attacks have always been attributed to catching cold or to digestive disturbance, though they sometimes occur without very evident cause. Any trifling cold, nasal or bronchial, is invariably followed by an attack, but diet has no such constant effect, though in three of the children the eating of vegetables or apples has very regularly produced it. Rhubarb,[3] black currants, strawberries,[4] &c., which have been reported as occasionally causing hæmaturia, have never given rise to an attack.

The exacerbation sets in suddenly, the child is feverish for a day or two and usually confined to bed, there is frequency of micturition, and sometimes enuresis, but never any complaint of pain. The child is well again by the third day as a rule, though occasionally the indisposition lasts from one to two weeks, or may be so slight that the child never misses school. During the attack the quantity of blood passed increases for a few days and then gradually lessens, and the urine regains its normal appearance by the end of the second or third week. Any general disturbance of the health at this time has invariably had the effect of prolonging the attack and increasing the quantity of blood (e.g., measles, whooping-cough, bronchitis), but exercise has no effect in this way, and the attacks are not more frequent or prolonged at one season than another. The quantity of urine passed daily in an attack is normal; the specific gravity is from 1015 to 1030, and the reaction neutral or acid. Albumin varies from 0·05 to 0·5 Esbach (to ¼ volume on boiling), and is in accordance with the blood present. The deposit, which is slight, contains many red blood corpuscles, abundant blood casts, an occasional hyaline cast, but no others; usually a few crystals of uric acid or of oxalates, and granular matter. There has never been œdema or dropsy at any time in any of the cases, nor pain on micturition, nor renal tenderness. The heart and vessels appear normal in all. None of them have suffered from scarlet fever, or rheumatism, or from gravel; and they have never shown any symptoms of scurvy, purpura, or Raynaud's disease. There is no history of other hæmorrhage in any of the cases. The other ordinary causes of hæmaturia (calculus, tubercle, syphilis, neoplasm, &c.) can be excluded.

type. She has had no other illness. The heart, vessels, and fundus are normal. The urine, which has been examined frequently, but only in the intervals, is slightly "smoky" in appearance and of acid reaction; the specific gravity is from 1015 to 1020, albumin 0 05 to 0 1

les and a few blood casts are

; hæmoglobin, 70 per cent.;

llimetre; white corpuscles,

per cent.; and polymorphonuclears, 57 per cent.

Of the other affected members of the family—i.e., of the younger grandson (No. 5 on the chart), aged 28 years, and his son, aged two years—I have no personal knowledge. From his medical adviser I learn that he has attended the elder during an attack of hæmaturia like those already described, and since the condition of the other members of the family became known the relatives have observed typical attacks in the child.

There is no doubt that these cases are of the same nature as those described by Guthrie in the paper already referred to. He reported a family of 15 persons of two generations, of which 12 members suffered from hæmaturia. Of the first generation (five persons) two males and two females were affected and one female unaffected. The males died, aged respectively 4½ and 11 years, from unknown causes; the two affected females married and had families. The elder had seven children, of whom five suffered from hæmaturia (four females aged 18, 15, 13, and 10 years, and one male aged six years); the younger had three children, (two males aged eight and three years, and one female aged 11 years), all affected. The attacks in these cases were usually attributed to catching cold and were associated with slight bronchial catarrh, or with earache, toothache, or tonsillitis. In some, certain articles of diet seemed to provoke an attack (claret, black currants, asparagus, strawberries). The hæmaturia seemed to produce no ill effects in any of them.

The three cases of recurrent hæmaturia in one family described by Atlee are referred to by Guthrie, who considers them of the same nature as his own, despite the absence of a hereditary or congenital history. They were three females, aged 5½, 4½, and 2½ years, one of whom had four attacks in nine months.

Although the hæmaturia may persist for years without materially affecting the health, beyond causing a slight degree of anæmia after a prolonged attack, yet none of my patients could be called robust. In only one of these seven cases has the hæmaturia disappeared, and since then the child's general condition has noticeably improved.

Remarking on the prognosis of these cases, Guthrie says, "the condition does not seem to endanger life, or even health, as a general rule." On the other hand, the father of Atlee's three family cases died from uræmia, and although there is no history of his having suffered from hæmaturia the association is suggestive. One of my own cases, a female, aged five years, died from acute nephritis with uræmia, and this in itself has necessitated a very guarded prognosis for the other members of the family. The report of this case is of interest, as the nephritis developed during an exacerbation of the hæmaturia.

[illegible] the day following was blood-red in colour, acid, [illegible] and albumin measured 0·1 Esbach ($\frac{1}{12}$ volume). [illegible] *many blood corpuscles, blood casts, and some* crystals of oxalates. Under treatment there were no further convulsions, though on the next day there was marked carpo-pedal spasm; the temperature was 101° F. and the tongue was very white and dirty. On the 9th the temperature was normal and on the 10th the child was running about apparently well. On the 14th I was called to see her again. She had been in bed for two days, taking only milk; the temperature was 100°, *the tongue was furred, and the bowels* were constipated. She had a cough, and sibilant râles were present all over the lungs. There was no change in the [illegible] gradually worse, and on the 18th [illegible] perature was 100°, the tongue was [illegible] smelling. On the next day she [illegible] delirium at times, and occasionally [illegible] and limbs. She passed no urine fr[illegible] On the 20th she was semi conscious; the temperature was 102°, the pulse was 120, of distinctly high tension, and the tongue was dry. The knee-jerks and superficial reflexes were exaggerated, Kernig's sign was present, and there was carpo-pedal spasm. The pupils were widely dilated, equal, and reacted sluggishly. The urine was blood-red in colour, of specific gravity 1032, acid, and had a copious deposit. *Albumin measured* 0·4 *Esbach* (¼ *volume*), *and* microscopically there were many blood corpuscles, blood casts, and abundant epithelial casts and epithelium. During the next three days the condition remained unchanged, despite treatment On account of enuresis the urine could not be measured, but was certainly less than normal. When conscious she complained of headache, there were frequent muscular twitchings and deviation of eyes and head to the right, and nystagmus was present. *Periods of consciousness, when the child drank greedily* and seemed better, were succeeded by periods of delirium, deepening to coma on the 23rd, when she died. The temperature (morning and evening) during the last four days varied from 102° to 103°, and the pulse was from 120 to 130 per minute and of high tension. On the day of death a [illegible] eruption appeared on the abdomen, legs, feet, [illegible] hands. The urine during the last four days [illegible] *of blood, epithelial, and granular casts, and* [illegible] 0·5 to 0·8 Esbach. There was no œdema or dropsy during the illness. A necropsy was refused.

In the absence of any post-mortem record, it must be uncertain whether these cases of hereditary hæmaturia are of vaso-motor origin,[5] or are due to structural changes in the renal vessels or tissues.[6] That the hæmaturia appears to be congenital and persistent, and that in the case above reported the symptoms of nephritis developed, seems to point to the latter suggestion rather than to the former.

Kilmarnock, N.B.

THE GENESIS OF THE MODERN INFIRMARY.[1]

BY F. S. TOOGOOD, M.D. LOND., D.P.H.,
BARRISTER-AT-LAW; MEDICAL SUPERINTENDENT OF LEWISHAM INFIRMARY.

FROM amidst the universal chorus of condemnation which arose when the report of the Royal Commission on the Poor Laws was issued there has been very little either said or written against the medical side of the service. There are many of us who remember how matters stood 25 years ago, and some of us have been told by our predecessors of the condition of affairs as they found them on their first acquaintance with Poor-law. Even those who are shouting most vehemently against the present order of things have, I notice, little in their condemnation which is derogatory to the medical work in which we are all so much interested. Truly we are not greatly praised, but after an experience of decades of professional aloofness and public apathy one has ceased to expect decoration or official recognition for services which for single-heartedness and devotion will bear comparison with those given in any other branch of civil service. Poor-law has ever been the Cinderella of the services, and the immense improvements which have taken place in the last fifty years have been effected by the medical officers themselves fighting, usually single-handed, against a hostile authority, and with superior officialdom unable to extend any effective support. I have no hesitation whatever in saying that the arrangements of a modern infirmary compare favourably with those existing at a general hospital; and certainly both for humanity and effectiveness the out-door Poor-law medical service is superior to the out-patient departments of our voluntary charities. Our service has nearly worked out its own salvation, and I see danger both to the community and to the medical profession as a whole if many of the suggested alterations receive the sanction of the public.

In the old days before the separation of the infirmary from the workhouse there was abundant scope for improvement in the treatment of the sick, but it must not be forgotten that even then things were little better in the general hospitals. There were no trained nurses. There were a certain number of poorly educated women who had drifted into sick-nursing generally because they had failed in other walks of life. There was no regular service of nursing as we understand it to-day. The higher female officials who held positions corresponding to the matrons, assistant matrons, and nursing superintendents of to-day were usually the inadequately provided-for widows of defunct local professional men or superior tradesmen. I have had it from an eye-witness that the night nurses of one of the most renowned hospitals in the United Kingdom habitually had wash-tubs in the ward and were responsible for the cleansing of a considerable portion of the hospital linen. With such a condition in the institutions which set the tone, what was to be expected of less favoured establishments?

The sick wards being part of the workhouse were necessarily under the jurisdiction of the workhouse master; he has been immortalised as Mr. Bumble, and the species is far from extinct, although education and a more enlightened policy on the part of electing boards have relegated him in great measure to the more inaccessible parts of the country. For a layman to be in supreme authority in an institution devoted to professional uses it is necessary, if chaos is to be averted, that both the layman and the professional element should be highly educated gentlefolk, endowed with absolute control over their tempers and possessing the power of appreciating and respecting the most delicate feelings of others. I have never yet found this happy combination of good qualities; and quite apart from the inherent absurdity of placing an uneducated person in a position where he was enabled to control men and women of superior education and attainments, there was an essential difference in their points of view, the one regarding every inmate or patient as someone to be "repressed," while the humanitarian training of the other had taught him to regard every sufferer as a fellow-being entitled to his respect, for whom it was his duty to put forth his whole power that he might cure him if possible, and at least give him comfort and peace.

The buildings were ill adapted for purposes of treatment; they were designed by architects whose ideas were actuated by the requirements of an eight-roomed house and who had no medical assistance to indicate what was required. Small wards, badly lighted with small inaccessible windows, apparently designed with the idea of preventing a patient leaving the building in an unconventional manner; fireplaces which would have efficiently adorned an artisan's best parlour; with the ward kitchen usually forgotten and the lavatory treated with the æsthetic consideration which demands that it should be made as difficult as possible of observation and therefore of access. The shell of the building was as a rule remarkably good and therefore adaptation to modern requirements has been found in some measure possible. The nursing arrangements were to our present notions deplorable. There were a few paid female attendants devoid of any trained knowledge of nursing and always too old and too engrooved to be capable of assimilating more than a rule-of-thumb method of instruction. As each of these women often had 100 sick persons under her care she neither could nor did perform any of the actual offices of nursing which were entrusted to old pauper women often imbecile, usually senile, and always worthless. Invariably a very heavy toll was levied upon any stimulant or delicacy ordered, while both patients and pauper nurses would save their brandy or whisky until visiting day and then have a grand carousal with their friends. So little real attention or inspection was bestowed upon patients that one woman successfully simulated paralysis for years; her affectation of piety rendered her an object of great interest to many benevolent visiting ladies, who showed their sympathy by giving her presents of sugar, tea, and snuff. These she hid in her flock bed. A freshly appointed medical officer, whose new broom was sweeping cleanly, earned an unsympathetic notoriety by insisting upon getting her out of bed, when many pounds of dry goods were found as well as several nests of mice. The patient recovered the use of her legs, which the nurses knew she had never lost, as she was often seen walking about at night, but such was the local belief in her sanctity that they were afraid to hint at the imposture.

[1] A paper read at the annual meeting of the Poor-law Medical Officers' Association of England and Wales held at the Guildhall, London, on July 6th, 1909.

The children under the old state of things probably suffered more than any other class. Left to the mercy of hags who drank their milk and grossly neglected them, their hold on life was rendered more precarious by the difficulty which the medical officer experienced in getting his orders duly executed. It will appear almost inconceivable that milk prescribed by the doctor was refused by the master and in some instances flour and water substituted. Representation to the board of guardians proving futile, one medical officer, the late Dr. D. M. Forbes, who related the circumstances to me, conceived the idea of refusing a certificate of death in every case where his instructions had not been faithfully carried out. The coroner zealously supported the efforts of the doctor, and the publicity so roused public opinion that the separation of the sick wards from the dominion of the master speedily resulted. Unfortunately lessons dearly bought are soon forgotten and quite recently the chairman of a powerful public authority in evidence before a commission advocated a return to lay superintendence. The reason is obvious: lay superintendence is naturally subservient to the authority of a board, its opinion is isolated and carries merely its own weight, whereas professional superintendence is dominant and compelling, and has behind it the power of a great organisation and cannot be lightly neglected. Fifty years ago the battle for the welfare of the patient was fought and won; if, unfortunately, it should become necessary to fight again I have no doubt either that the man will be forthcoming or that the victory will be ours. In the midst of strife and contention it is well to be able to appreciate the humorous aspect of the situation. Dr. Forbes used to relate the following circumstance with great relish. At a time when relations between himself and the workhouse master were strained, the latter used to take every opportunity of making the doctor's life uncomfortable, and one of his tricks was that of disturbing his rest by needlessly calling him up at night. This needed collusion with the attendant upon night duty, which in this instance was forthcoming. Night after night, and many times in each night the unfortunate doctor was roused from his bed to see patients who obviously [illegible] It was impossible to complain the [illegible] advice of the doctor was necessary, it was obviously impossible for him to resent it openly. Had the board been friendly it could not interfere with the discretion of an officer expressly charged with the duty of looking after sick at night, and in this case the board was the reverse of friendly. The canny Scot, however, gauged the situation. He saw that he must make the process of calling him involve discomfort to the master and attendant as well as to himself. At first, therefore, he ordered for every suitable case beaten-up eggs; this necessitated the master being roused to go to his stores and also gave the attendant the job of manipulating the eggs to the required consistency. This answered for a time, but not for long, as the enemy forestalled him by preparing ammunition in the day-time. A renewal of the disturbance was met by the prescribing of brandy; this was successful inasmuch as the master was compelled to rise for each portion ordered, as he could not trust it in bulk to the attendant, but from an unforeseen reason it defeated its object, for when the patients found that being suddenly taken ill at night meant brandy, a large number of adventurous spirits speedily and frequently developed alarming symptoms The next move was, however, final and decisive; it consisted in ordering crushed ice poultices. Now there was only one ice chest and that was in the basement far from the master's bedroom, the process of crushing ice is laborious, and the wearing of an ice poultice is not eagerly sought for. Hence the final victory remained with the medical man.

To persons unaccustomed to institution life this may seem rather "small beer," but I introduce it merely as one illustration of the many circumstances which render it imperative that establishments for the treatment of the sick should be under medical control. Half a century ago the professional education of a medical man was not to be compared with that demanded of him to-day. Hence the cases, both medical and surgical, found in workhouse sick wards were quite ordinary in character, mainly those incidental to childhood and old age occurring amongst the inmates of the workhouse Patients needing surgical operations were transferred to the nearest hospital, and necessarily so because, even if the medical officer had the requisite skill and experience, the appliances and nursing were lacking. The medical officer's contract frequently stipulated that he should supply drugs and surgical instruments, and this for a salary which was invariably beggarly in amount Even in those instances where the guardians were responsible for supplying materials the hospital idea had not yet evolved itself, and sick wards contained merely inmates of the workhouse who were out of health and required some special attention and diet. But with the separation of the sick wards from the ordinary workhouse administration, which resulted in the establishment of separate infirmaries, a gradual transformation was commenced which has progressed until to-day the best of our London infirmaries are clinically equal to any of the general hospitals. The evolution was somewhat slow, for many changes were necessary and the needful combinations required time to eventuate. Firstly, it was requisite that the doctor appointed should have had special institution training; the power to govern a large staff successfully is only acquired by years of experience, and a good administrator must be caught young and must grow up in the atmosphere. Those superintendents who have failed as administrators, and who have incidentally been cited as examples of medical inability to govern, have been men who have been unwisely translated from general practice without having served the needful and essential apprenticeship. Naturally it took some years to create a supply of these trained men. The nursing staff slowly grew into proficiency. There was at first little to attract desirable women to the service of an infirmary. The workhouse associations were still strongly in the public mind. It was not yet considered essential that the matron should be a trained nurse, and as the appointing authority usually elected a local female whose indigence was her chief qualification, she was usually a very indifferent housekeeper. It was obviously impossible to expect trained nurses to serve under a woman with no training, so the best class of nurse was never forthcoming even as head nurses, while for assistant nurses the flotsam and jetsam from fever hospitals, failures from general hospitals, and ward maids with some smattering of knowledge alone were available.

Marylebone Infirmary initiated a system whereby women known as "Nightingale nurses," having received a year's training at St. Thomas's Hospital, were transferred to Marylebone Infirmary to complete their professional pupilage. The Workhouse Nursing Association, now, I believe, defunct, supplied some infirmaries with young women who had received a year's training in nursing at some medical institution. Those infirmaries who availed themselves of this supply were enabled to tide over a difficult period of their history, but the condition of dual authority which the arrangement involved did not work well in practice, and the infirmary authorities one after the other secured their nursing staff by establishing a training school for nurses and by granting certificates for proficiency in nursing. The confidence of the medical profession and the public in the infirmary was growing. The increase in the number of admissions necessitated the appointment of additional medical officers, at first one assistant, but latterly in most infirmaries there are two, and in some, where additional duties have been placed upon the administration, further medical officers have been sanctioned. The constant succession of young practitioners fresh from hospital has been useful in keeping up a spirit of modernity where otherwise there would have been a tendency to stagnation. Undoubtedly in the earlier appointments of medical superintendents the posts were not filled by the best men obtainable—local interests were allowed to predominate; but in recent years there has been no lack of first-rate candidates and little fault could be found with the local boards in their ultimate selection. With the institutions staffed by conscientious and capable men, with trained nurses appointed as matrons, and with young well-educated women as nurses, the tone of the institutions changed vastly for the better, and as a consequence the class of person admitted as patients included many who could not rightfully be designated paupers, and insensibly the stigma of pauperism has detached itself from the infirmaries.

There are two circumstances which determine the character of an infirmary: firstly, the presence or absence in the neighbourhood of a general hospital; and secondly, the energy and ability of the infirmary medical staff. Some districts are abundantly served by general hospitals, and there the infirmary patients will be found to consist mainly of persons suffering from chronic and incurable diseases; there will be few acute cases and little or no surgery; whilst the social status of the majority will more closely approximate to that of the ordinary workhouse inmate. But in a district remote from a general hospital, especially if the infirmary medical staff be keen, the local medical practitioners and the general public speedily discover that all emergencies can be dealt with in the local institution and soon the patients, both in social status and in the nature of their diseases, can scarcely be differentiated from those of a general hospital. Curiously enough, the better the class of patient the less are the individuals affected by whatever stigma of pauperism there is remaining. Two circumstances appeal largely to the patients. Firstly, the fact that the infirmary is near to the homes of their friends, and therefore they can be visited easily, frequently and with little expense; and, secondly, the restfulness of the infirmary wards. The patients in a general hospital—I am speaking of those to which a medical school is attached—are naturally objects of interest from a clinical point of view, and the larger the numbers of the staff and the students, the greater is the amount of time spent in examination of the patient; consequently a really interesting "case" becomes speedily "fed up" with the amount of attention bestowed upon him by enthusiastic investigators. The continuous examination, although often grateful to the patient at first, is speedily regarded with aversion, a feeling which is sometimes vented upon some unlucky student who has the ill-luck to have the case allotted to him for examination purposes.

It has been stated that there is a wealth of material in infirmary wards which ought to be utilised for research and for teaching purposes. It is a mistake to suppose that infirmaries contain cases which are not to be seen in general hospitals; this is not so. In my long experience I have seen no cases which I had not previously seen as a student at University College Hospital, either in the wards or in the out-patient department. Certainly, we see the end of many cases which the hospitals are unable to retain, and we often devote years of attention to surgical cases which leave general hospitals as "cures." So far as research is concerned, the pages of the medical press and the proceedings of the various societies bear witness to the interest which the infirmary medical staff takes in unusual conditions of disease, and permission is never refused to genuine investigators who desire to prosecute inquiries in definite directions.

As to teaching, I am not aware of any real demand. I know, of course, that there are many medical men, whose ambitions exceed their opportunities, who would like to have the run of infirmary wards. It must be remembered that the primary object of an infirmary is to provide treatment for the sick poor, and that there has been no genuine demand for the utilisation of the infirmaries as teaching centres, the reason being that for various well-recognised causes there is a comparative shortage in the number of London medical students, and that for some years past there has been barely a sufficient number to carry on the necessary work of the general hospitals. When a demand for teaching really arises the medical staff of the infirmaries will be found sufficiently keen to undertake the work. The relatively large number of pathological examinations made is an evidence of the interest taken by the staff in their work.

Nor only are the infirmaries responsible for all the work usually undertaken by general hospitals, but they have in addition to provide accommodation for those infectious diseases which are not admitted into the hospitals of the Metropolitan Asylums Board. The latter authority deals with scarlet fever, diphtheria, enteric fever, small-pox, and probably with cerebro-spinal meningitis and typhus fever, leaving to the Poor-law guardians the care of measles, chicken-pox, whooping-cough, erysipelas, and puerperal fever. It is not at all an uncommon thing for an infirmary to have 40 or 50 cases of measles for which room has to be found.

Some of the best work of the service has been performed in the treatment of the mentally affected. So far back as 1891 I advocated and carried out the detention of all cases of lunacy for the full statutory period of 17 days before passing them on to an asylum; this has now become a general practice and roughly one-third of the total admissions to the mental wards require transference to an asylum. The agitation of the London County Council for receiving houses was entirely uncalled for, the work was already in being, and the good effects for which they hoped had already been achieved. This was abundantly recognised by the Royal Commission appointed to consider the working of the lunacy laws. With few exceptions, properly equipped mental blocks exist in all London unions and the small percentage of cases ultimately confined in asylums is a striking evidence of the success of the treatment.

In view of the remarks of the Minority Report of the Royal Commission I feel I must notice the work of the lying-in wards. The infantile mortality-rate has been compared unfavourably with that obtaining at certain lying-in hospitals. In order to make a fair comparison similar conditions must prevail in the institutions compared. I am informed that in the special lying-in hospitals of London the patients are mainly married women of undoubted respectability and therefore may fairly be called "picked cases." The admissions to a Poor-law lying-in ward include many of the most unfavourable type. Prostitutes rotten with disease, girls who have fallen and who have run the whole gamut of misery from shame and exposure before seeking admission, and who have usually exhausted every available means of terminating the pregnancy, not excluding mechanical interference. A considerable proportion of our cases are primiparæ, and in this district many are sent in by the outside doctors because it is known or anticipated that the labour will be difficult. Now all this information could have been obtained in an exact form by the Commission had it been so minded; certainly its deliberations do not appear to have been characterised by undue haste, and yet a most damaging statement has been issued and widely copied, supported by statistics which are partial and misleading. One-third of the unions are left out altogether and the amazing assumption is made that the children who leave the workhouse or infirmary will die at the same rate as those who remain. A frequent reason for the continued presence of mother and child is the weakly condition of the latter. It is also no uncommon thing for mother and child to leave the lying-in wards at the end of the customary three weeks in perfect condition. The mother returns to her work and the baby is placed out to nurse. It happens frequently that in a few days the child is readmitted to the infirmary in a moribund condition, wofully neglected, and dying from improper feeding. Many of the mothers and babies are transferred to the workhouse, where the former are placed upon a liberal diet, and although apportioned some task either of washing or cleaning, yet the care of the child is regarded by the authorities as the first demand upon the mother. There is, however, no power to prevent her from taking her discharge whenever she thinks fit to do so, and the result usually is that she drags the unfortunate baby about from early morning till late at night with no means of attending to the cleanliness of the child or of supplying it with food. Its condition on their return is deplorable, soaking in filth and inflamed and excoriated to such a degree that weeks of care are required to nurse it back to health, while the wholly improper food taken on these excursions often starts an enteritis which terminates fatally in a few days. I have known a woman give a three months' old baby a meal of beer and boiled French beans from the effects of which the child died. Where the authorities have so little power, is it playing the game to saddle them with the responsibility for affairs over which they have no control?

To return to the consideration of infirmary work proper, I find that there were in the metropolis 26 infirmaries containing 14,863 beds treating 79,111 patients in 1908, employing 1756 nurses and performing over 3500 operations annually under anæsthetics. The number of operations varies greatly, ranging from 12 to over 600. Locality has much to do with the variations in numbers, but the policy of the board of guardians and the inclination of the medical staff are not without their influence. Whilst I am exceedingly proud of the good work which is being done by the numerically small staffs of our infirmaries, I may perhaps be allowed to indicate in what direction improvements might be effected. I see no reason for mixing us up with the sanitary authorities, whose experience of clinical medicine and surgery terminated with the acquisition of an academic qualification and whose subsequent functions have been more clerical than clinical. The Tuberculosis Order of the Local Government Board suggests methods by which the health authorities may keep in touch with suitable cases after they have left the infirmary with a view to encouraging the patients to continue the exercise of those hygienic measures which they have learnt during their stay in the infirmary wards. London should be dealt with as a whole; the present areas are too small for effective treatment. This would give an opportunity for more economical dealing with disease by enabling some specialisation in treatment to be accomplished. The capacities of existing buildings and the capabilities of persons would then be more efficiently utilised than by the present system, which compels each building to accommodate every disease with the exception of those few for which the Metropolitan Asylums Board is responsible, and which assumes that the medical officers combine in their two, three, or four persons the tactile dexterity and potential energy of a full hospital staff. By judicious grouping considerable economies could be effected. Against this it must not be forgotten that the poor cannot travel great distances to visit their friends and that the transportation of patients for lengthy periods would mean the infliction of considerable hardships.

At present there is little or no coöperation between the outdoor and indoor medical staff, that is, between the district medical officers and the infirmary medical officers. About 15 years ago, in St. George-in-the-East parish, a whole-time medical officer was appointed to attend the outdoor sick poor in one of their more crowded districts; there was, however, no system of coöperation between the outdoor and the indoor staff and the arrangement soon reverted to the part-time district medical officer plan. In Lambeth, however, for some years past, the centrally situated districts have been ministered to by medical officers working from the infirmary under the supervision of the medical superintendent. By this arrangement the administration is made much more smooth. The home circumstances of the patients are known and the frequent discharges and re-admissions are avoided. Often a patient's physical condition [illegible] and [illegible] be [illegible] consequently the district medical officer sends him in again immediately. There being no channel of communication between the district medical officer and the infirmary, the one has no conception of the needs and difficulties of the other, hence there is the risk that they sometimes play at cross purposes. As matters stand the district medical officer has a distinct inducement to send patients to the infirmary, his visiting list is thereby depleted and his leisure is greater. The same argument may, I know, be used to the discomfiture of the indoor staff, but with less truth, as 10 or 20 patients more or less in a building make little difference. I regard the question of whole-time or part-time district medical officer as of little importance, but I think it essential that there should be a central point from which all the work should radiate and the infirmary would appear to be the proper headquarters. I believe a considerable economy in beds would be effected; any temporary overcrowding of the infirmary would be met by the [illegible] their own homes. This, through [illegible] is at present impossible. The [illegible] medical officer a stated salary, to include the provision of medical attendance and of medi- [illegible] and it [illegible] their [illegible] at the community is sweating the hard-worked, under-paid medical officer, who has to defend himself by any method open to him.

I have said nothing about the salaries of the infirmary medical officers, and I will now only suggest that I see no reason why the rate of pay should compare so unfavourably with that given to officers holding a similar position in the service of the Metropolitan Asylums Board and of the county asylums. Men who yearly each perform some 300 or 400 major operations are receiving salaries often only one-third, and never more than one-half, as large as those paid by the county boards. It seems to be inevitable that Poor-law officers should be themselves poorly paid. By a curious association of ideas it has come to be regarded as fit and proper that the repressive and deterrent methods which have so long prevailed in Poor-law should apply also to the treatment of officials. Some months ago the less expensive papers waxed indignant over the statement that the nurses of a Poor-law institution received an occasional pineapple as part of their rations. The confusion of ideas [illegible] three half-pence [illegible] the disheartening [illegible] a widely spread feeling that the circumstances of a Poor-law official should not form any strong contrast with those of the class for whose welfare he is responsible. The guardians themselves, or at any rate many of them, resent the circumstance of an official receiving a larger income than they themselves command. The Royal Commission quotes the remark, "He is our servant, and he gets more money than his master." If he succeed in convincing his immediate board that he is worthy of greater recompense his application has still to pass the custodians of the public purse at the Local Government Board, who appear to have a standard of payments based upon the idea that Poor-law medical officers have large private incomes and that this official work is undertaken by them as a recreation. It is most disheartening, after local opinion has recognised one's worth, to find that the report of one's fame has not penetrated into the corridors of Whitehall.

In conclusion, may I express the opinion that the Poor-law medical service does its work efficiently and at a very small cost to the community, and that whatever faults were found with the system by Dr. McVail exist with equal force in hospital and out-patient practice. Efficient supervision can only be secured in out-patient practice at an enormous cost. The medical officer's function is mainly advisory; he cannot compel his patient to follow his advice whether he be a pauper or a peer. Both reports of the Poor-law Commission appear to believe that by calling Poor-law by some other name and by transferring the work to some other authority they have changed the system, but beyond and behind this there are the personal characteristics of the people and the economic conditions from which society is suffering. These will not be altered by the changing of a name nor obliterated by transferring work to bodies devoid of experience.

Lewisham.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ACUTE PANCREATITIS WITH FAT NECROSIS.

BY F. W. GOYDER, M.B. CANTAB., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, BRADFORD ROYAL INFIRMARY.

[illegible] was admitted into the Royal Infir- [illegible] week after the beginning [illegible] lth until after the birth [illegible] usly. Since this time she had occasional attacks of abdominal pain and vomiting, never being free for more than two months. The history of the present attack was vague; it began suddenly with abdominal pain. She vomited daily and her bowels were constipated until admission. There had been no jaundice and no injury. When admitted into the hospital she complained of epigastric pain, not severe or constant, and looked acutely ill, but with the appearance of previous good health. Examination was difficult owing to her fat. The abdomen was distended, slightly tender in the right loin, and more resistant on the right side than on the left. There was lack of resonance in the right upper quadrant, hyper-resonance elsewhere, and no iliac tenderness. The temperature was 98·8° F., the pulse was 100, and the respirations were 36. Leucocytosis was absent. During the next two days the distension varied, the bowels were moved, but vomiting of greenish fluid continued. After this the temperature rose, [illegible] the vomiting ceased, and the bowels [illegible] were light coloured, bulky, and offensive, with no obvious fat and only occasional curds. The patient's chief complaint was difficulty in breathing, which was worse at night. Her respirations became rapid, but there was no cyanosis. Dyspnœa varied with the distension. Up to the end of June this condition persisted; the temperature, always above normal, rose at times to 102°, with morning remissions often of 2°. Dulness and crepitations were heard over the bases of both lungs.

A diagnosis was made of abscess in the right loin, secondary perhaps to appendicitis. A needle introduced in the right loin withdrew a brownish fœtid fluid containing débris with a few acicular crystals, and no evident pus or blood. Her condition precluded extensive manipulation, but an incision into the loin was rewarded by the discovery of an extensive cavity containing similar fluid and cohesive brownish masses resembling blood clot. The œdema of the feet previously present disappeared temporarily after operation. The wound discharged the same kind of matter. Respiratory difficulties, increasing cardiac insufficiency, and general weakness resulted in her death six weeks after the onset of the illness. Throughout there was no jaundice; the stools, though pale, contained bile, and the urine a small quantity of albumin, but no sugar.

On post-mortem examination the thoracic cavity was much encroached on by the distended abdomen; the lungs were congested at the bases but not consolidated. The peritoneal cavity was normal. No spots of mesenteric fat necrosis were seen; the liver was large, soft, and fatty; the gall-bladder was thickened, unusually fixed, and contained many gall-stones. The ducts appeared to be free; the appendix was normal and the intestines without sign of lesion. Retroperitoneally, communicating with the sloughing operation wound, was an irregular cavity with necrotic walls. It was roughly H-shaped, the right-hand limb extending from the iliac crest, behind the liver, to the diaphragm, the connecting limb surrounding the pancreas, and the left limb lying behind the spleen and the descending colon. The pancreas was large, hard, and fibrous, without sign of hæmorrhage, the head densely adherent. The contents of the cavity were like those found at operation—they had neither the appearance nor the smell of an ordinary abscess. The odour, although unlike that of a bacillus coli infection, was no less offensive. I cannot describe it, but I should know it again.

If I am correct in my reading of the case, the following was the order of events: (1) gall-stones with one or more attacks of cholecystitis; (2) a secondary pancreatitis; (3) a pancreatic lesion causing escape of the secretion behind the peritoneum; and (4) retroperitoneal necrosis of the abundant fat in this region with formation of the tumour in the right loin.

The difficulty in the diagnosis of such cases is well known. An acute abdominal catastrophe is usually the most that can be made out in the severest cases; intestinal obstruction or appendicitis are commonly diagnosed. The unusual features in this case are the comparative lack of severity of the onset and the long course. Of the latter, however, Moynihan says: "Gangrene and diffuse suppuration are to be considered only as terminal phases, and not as special forms of acute inflammation of the pancreas."[1]

Bradford.

A CASE OF PURPURA HÆMORRHAGICA FOLLOWING THE USE OF FIBROLYSIN.

By S. Clifford Pritchard, M.D. Edin.

With a Note by Sir James Reid, Bart., G.C.V.O., K.C.B., M.D., F.R.C.P. Lond.

The patient, who was 69 years of age, complained of Dupuytren's contraction in both palms; in the left hand the condition was so advanced that the terminal phalanx of the ring finger touched the palm; in the right hand the affection was just commencing. It was decided to try to reduce the contractions by fibrolysin. The first injection of 2·3 cubic centimetres (as obtained in sealed glass tubes) was made on March 27th, and a second one on April 1st. It was repeated on April 5th, and then every third day until May 20th, making 18 injections in all. The palms were massaged every day. The condition slowly showed signs of improvement, the left especially becoming softer and less tied down. On May 19th there was a slight epistaxis, while on the 21st the patient had a slight bleeding from the gums and a few purpuric spots appeared on both legs. He was given calcium chloride (10 grains every four hours). On the 22nd the bleeding from the gums was rather more profuse, and there were more purpuric spots on the legs. On the following day the bleeding from the gums increased, there were more purpuric spots, and for the first time there was hæmaturia. Passing urine was also very painful. Calcium lactate (10 grains three times a day) was given as well as the calcium chloride. On the 24th, as all the symptoms continued, it was decided to give the patient a mixture containing perchloride of iron (7 minims every two hours), together with 30 grains of calcium chloride twice a day; an alum mouth-wash was also prescribed. On the 25th there was a slight improvement in the hæmaturia and also in the bleeding from the gums. The same mixtures were continued and hazeline was substituted for the alum in the mouth-wash. On the 26th a very great reduction of the bleeding both from the gums and in the urine took place, and on the following day the bleeding entirely stopped. The patient, who had taken only liquid food until now, was able to manage soft solids. The temperature had remained normal throughout, but the pulse, which at first was 72, had gradually increased to 90, but was quite regular. The arterial tension had been at first very high but gradually became less and was now a little below normal. On the 28th there was still no bleeding. A mixture containing nux vomica and nitro-hydrochloric acid was substituted for the perchloride of iron. The pulse remained good, but the patient was restless and seemed inclined to wander. On the 29th early in the morning the pulse became very irregular and occasionally intermittent, and from now onwards it gradually got weaker and faster, with short intervals during which it was quite regular and of good tension, until on the afternoon of the 30th death occurred.

Note by Sir James Reid.—This patient, whom I saw several times in consultation with Dr. Clifford, had for some years been the subject of glycosuria, as well as of occasional slight albuminuria. In January the amount of sugar present was found to vary from 1½ to 3½ grains per ounce and was kept under by a modified dietary. (When the injections began neither sugar nor albumin was present.) He also had a systolic aortic murmur, and for a year had been subject to occasional anginal attacks which came on only when he was walking, obliging him to stop, when they passed off. The exhibition of trinitrin, varied by sodium nitrite, had been followed by a reduction in the frequency and severity of these attacks. When the first purpura appeared the amount of sugar present in the urine was found to have risen to 8 grains per ounce, and the question arises whether the presence of sugar in the blood may have created a special vulnerability to fibrolysin, and whether there was any connexion between the injection of fibrolysin and the rise in the amount of sugar present.

A CASE OF TETANUS TREATED WITH ANTITOXIN; RECOVERY.

By Robert C. Pitt, M.R.C.S. Eng., L.R.C.P. Lond.,

SURGEON TO THE MALMESBURY COTTAGE HOSPITAL.

On April 8th a man, aged 42 years, came to see me and complained of stiffness in the jaw which he attributed to injuries he had received on March 18th whilst fighting with another man. He also had a small wound on the bridge of his nose which had practically healed. On the 11th I was sent for to see him and all he complained of was backache and stiff jaw. I saw him again on the following day, when definite signs of tetanus had developed. He complained of stiffness in his neck, back, and legs and "awful cramps."

On April 13th the patient was admitted to the Malmesbury Cottage Hospital, and on examination presented the following signs. The muscles of the jaw were stiff and rigid and fixed. The neck, back, and legs were absolutely rigid so that if his feet were raised he rested on the back of his head, and his abdominal muscles were as hard as a board. His pulse was not quickened nor his temperature raised. He was placed in a ward by himself, the room was darkened, and a nurse was in constant attendance. As much nourishment as he could possibly take was given him in the shape of concentrated meat-juices, milk, eggs, and stimulants which were passed through a fine tube into his mouth 30 cubic centimetres of antitoxin were injected into the skin of the abdomen on three consecutive days. The painful spasms were relieved by morphia and his constipation by aperients Three days after the third injection of antitoxin a [illegible] developed (antitoxin rash) On the 24th he was able to [illegible] his left knee. On the 26th he complained of great p[illegible] the bowels and had frequent diarrhœa which lasted two days. This was relieved by a large dose o[illegible] few drops of laudanum. On the 29th he [illegible] a [illegible] (the 30th) he was [illegible] The vomit was at [illegible] He was collapsed, his extremities were cold, the pulse was very rapid, and the temperature was subnormal. Nutrient enemata and stimulants were administered by the rectum. When I saw him the next morning the vomiting had ceased and I found [illegible]

Reviews and Notices of Books.

Special Hospitals: Their Origin, Development, and Relationship to Medical Education; their Economic Aspects and Relative Freedom from Abuse. By RICHARD KERSHAW. London: George Pulman and Sons, Limited. 1909. Pp 72. Price 2s. 6d.

Mr. Kershaw, who is the secretary of the Central London Throat and Ear Hospital, is naturally a warm advocate for special hospitals, and his unassuming little monograph certainly pleads their cause with eloquence. He commences by giving some historical instances of specialism, referring, of course, to the famous passage in the second book of Herodotus about specialism in Egypt. In places Mr. Kershaw is led into looseness of expression, as, for instance, on p 20, where he says, "In the fifteenth and sixteenth centuries, the renaissance of medical science led to the establishment of universities and to the foundation of medical corporations," as if neither of these bodies had existed previously. Now all the great European universities were founded long prior to the fifteenth century. Bologna, Paris, and Oxford were all founded in the twelfth century, as was Montpellier, which was for many years the greatest European medical school, with the possible exception of Salerno. Further on Mr. Kershaw says that during the same period so little had medicine developed that at the Universities of St. Andrews and Glasgow it was held to be a section of the faculty of theology, from which it was not separated "until at the University of Aberdeen the first professor of medicine and the only teacher of medicine then in Britain was appointed. . . ." Mr Kershaw does not give the date of this appointment The University of Aberdeen was founded in 1494, and if this date or one within some 15 years later is meant, Linacre was probably lecturing on medicine at Oxford. He returned to Oxford from Italy after 1491, and Wood says that he was lecturing, though he does not specify in what subject, in 1510 We think that "the only teacher of medicine in Britain" is too bold a statement With regard to the mention of medicine as a department of the faculty of theology, this implied no disrespect. Medicine and the priesthood had been closely connected all through the middle ages for the simple reason that a religious house was about the only place where a man had the leisure to study, and, moreover, the clerks were about the only members of the community who could read. Many eminent clerics studied medicine, such as Grossetete and Roger Bacon, and conversely, many eminent medical men [illegible]

"Inhabitants c[illegible] House Tavern. [illegible] hospitals are proportionally more expensive than general hospitals, Mr. Kershaw, though quite alive to the fact that it is not fair to judge of the efficiency of a hospital by its economy, shows that, taking 15 general hospitals and 31 special hospitals, the cost per in-patient per week in the former is £1 17s. 4d and £1 13s. in the latter, while an out-patient in a general hospital costs 7¼d. per attendance and in a special hospital 8½d.

In his last chapter Mr. Kershaw deals with the matter of abuse of charity. In his opinion, the special hospital is free from this abuse, and he gives some figures from the records of the Central London Throat and Ear Hospital which certainly show that the institution is valued by medical men. During the year 1908 there were 10,481 new out-patients and 706 in-patients Of the former, 3067 and of the latter 392 were sent in by medical practitioners. The book ends with a tabulated list of special hospitals founded during the nineteenth century in the United Kingdom, with figures for 1907 showing the proportion of patients sent by medical men. These figures show that medical men send patients in large numbers to the special hospitals, in which case the institutions "may reasonably claim exemption from any charge of abuse or injustice," says Mr. Kershaw with considerable force.

In the chapter wherein the author deals with specialism and medical education, there are given figures showing how the special hospitals are sought after by medical men and post-graduate students, and the chapter ends with a quotation from Sir James Paget's speech at the International Medical Congress of 1881 wherein he argued forcibly in favour of true specialism. The increase of knowledge, he said, was greater than that of mental power, and "for complete knowledge .. no one can hope for success unless by limiting himself within the few divisions of the science for which by nature or by education he is best fitted" Given a good general foundation, specialism is now almost a necessity for a comprehensive knowledge of any branch of medicine, and Mr. Kershaw's book marshals the arguments for it in a quiet and dignified fashion.

The Last Days of Charles II. By RAYMOND CRAWFURD, M.A., M D. Oxon., F.R C P. Lond. Oxford: At the Clarendon Press. 1909. Pp 80. Price 5s net.

THE study of the medical aspects of the deaths of prominent persons is one which is always of interest, especially when, as in the present case, the matter is surrounded by doubts which are by no means easy to clear up Of old time the only historical studies of deaths that had any medical aspect about them were flavoured with the odium theologicum to an extent which made them, however interesting, extremely untrustworthy, to say nothing of the remarkably vague notions of medicine which prevailed even until the eighteenth century. We need only refer to Lactantius with his "De Morte Persecutorum" and in later times to a delightful little eighteenth century work called "God's Fearful Judgements upon Tyrants and Sinners" as examples. But the book now before us is written by a scholar and an able physician, and deals with a matter upon which there is only too much evidence rather than too little. As Macaulay says, "Whoever attempts to digest this vast mass of materials into a consistent narrative will find the task a difficult one."

Dr. Crawfurd's view is as follows: "One may assert, with considerable confidence, that his (Charles') death was due to chronic granular kidney (a form of Bright's disease) with uræmic convulsions." It is easier to say from what disease Charles did not die than to state the contrary. It was certainly not apoplexy, if that term be confined to cerebral hæmorrhage, and there was no definite evidence of poisoning—a mode of death which was, of course, suggested at the time. In regard to this latter point, we note that Dr. Crawfurd says that the treatment as laid down in Scarburgh's MS. shows "that those who directed the treatment had no suspicion of poison in their minds." Towards the end of the illness, however, both Goa stone and bezoar were prescribed, which look as if some one had thought of poison. Dr. Crawfurd's theory of uræmia certainly covers most of the symptoms described, and the account of the condition of the brain as found at the post-mortem examination would fit in with uræmia. On the other hand, the King's mental condition throughout to within the last two hours of his life is very unusual in uræmia, for he maintained all his faculties to the end, and except when seized with the convulsions, which seem to have been epileptiform, he was perfectly rational and capable of discussing the most serious matters.

However, it would be difficult in the case of any patient, be he a king or a beggar, to separate the symptoms due to disease from those due to treatment such as the unhappy King received. He was taken ill on the morning of Feb. 2nd, after that Sunday night so forcibly described by Evelyn, and while in the convulsion was bled by Edmund King to 16 ounces with immediate good effect. By this time some six of the king's physicians had arrived. His Majesty was then cupped, given an emetic, a drachm of colocynth and scammony pill, and an enema. After one or two hours the enema was repeated and also the pill. In addition, to use Scarburgh's words, "ut nullum lapidem immotum relinquerent, applicata etiam fuerunt Epispastica universa Capiti derasis prius Capillis." As the day went on he was given more purgatives, including hiera picra and cream of tartar, another enema, spirits of sal ammoniac, and "cephalic plasters" to the soles of his feet. On Tuesday he was bled again, and his bowels were kept continuously relaxed with hiera picra and manna. On Wednesday and Thursday he was given a little rest, and on the Friday he was only given stimulants, Goa stone and bezoar. He died about noon. There was not much belief in the *vis medicatrix naturæ* in the seventeenth century and drugs were practically everything. Hiera picra (the very name shows in what esteem it was held) was and had been for many years the purgative *par excellence*—in fact, its name was applied metaphorically, as, for instance, the title of a twelfth century satire on the clergy, written by one who was at once a clerk and a physician, was "Ierapigra Magistri Egidii de Corboilo ad Purgandos Prelatos." The name, and practically the thing, has survived in the popular term "hickery pickery," and its chief constituent is aloes.

Scarburgh says practically nothing of the symptoms. Dr. Crawfurd gives the Latin text of his original MS. with a translation. Welwood, who was a physician, says that Charles had previously suffered from "fits." Some of these, as Dr. Crawfurd shows, were undoubtedly ague fits, but Welwood gives an account of one fit which was evidently epileptic. During the time of the Popish Plot Charles had an interview with a Romish priest, who came out of the royal closet looking very much alarmed, and, on being interrogated, said that while he was with the King "His Majesty was suddenly surprised with a Fit, accompanied by violent convulsions of his body and Contortions of his Face, which lasted for some Moments ...... and the King ...... bid him not to be afraid, for he had been troubled with the like before." Welwood also says that during the whole of his illness he complained of a racking pain in his stomach, which apparently came on just before the first fit. Could this have been of the nature of angina? Afterwards it might well have been caused by the amount of purgatives. On the whole, then, though uræmia seems to offer the most likely solution of the mystery, we do not think that it can be said to be an absolute one. Dr. Crawfurd adds to the value of his monograph by a memoir of Scarburgh illustrated by a reproduction of a picture of that physician with Arris engaged in a demonstration. Scarburgh is represented sitting in his Doctor's robes and the picture is interesting as apparently he is wearing the fur-lined cappa, a garment which has unfortunately disappeared at Oxford, although Cambridge still retains it for her Vice-Chancellor on degree days.

We congratulate Dr. Crawfurd upon an able piece of work and need only add that the printing and paper of the book are, as is only to be expected in a work issuing from the Clarendon Press, excellent in every way.

American Practice of Surgery: a Complete System of the Science and Art of Surgery by Representative Surgeons of the United States and Canada. Editors: JOSEPH D. BRYANT, M.D., LL.D., and ALBERT H. BUCK, M.D., of New York City. Complete in eight volumes. Profusely illustrated. Vol. IV. New York: William Wood and Company. 1908. Pp. 1010. Price 7, 8, or 9 dollars, according to binding.

WE can only repeat the favourable opinion which we have expressed of the previous volumes of this treatise. This instalment is one of the more important, for it includes the chapter on dislocations extending to 100 pages, the general article on operative surgery occupying 500 pages, and a chapter on orthopædic surgery which fills some 400 pages.

The section on dislocations has been written by Dr. Emmet Rexford of San Francisco and it contains a good account of these lesions. It has a large number of illustrations, and many of these come from Helferich's well-known work. Dr. C. B. G. de Nancrède of Ann Arbor, Michigan, is responsible for the chapter on the influences which should be taken into account before an operation is undertaken; and in it he discusses the environment, the personal qualifications of the operator and assistants, operations "à deux temps," medico-legal considerations, and the influence of the condition of the heart and blood-vessels, of the gastro-intestinal, the genito-urinary, and the nervous systems. The effect of disease of the lungs is also discussed. Dr. George B. Johnston of Richmond, Virginia, has written on the preparation for an operation, and on the care of the patient during and immediately after an operation. It contains many useful suggestions. The article on anæsthetics is the joint production of Dr. Freeman Allen and Dr. F. E. Garland of Boston, Massachusetts. A short sketch is given of the history, and then a very full account follows of the use of the several anæsthetics; it is written with great care and represents very closely the received opinions on anæsthesia. Dr. J. F. Mitchell of Washington has contributed the chapter on local anæsthesia; he maintains that the various methods of local anæsthesia have not been appreciated as they should. He describes all the ordinary methods, but the description of spinal anæsthesia is hardly sufficiently full.

Dr. W. L. Rodman and Dr. J. S. Rodman of Philadelphia are responsible for the excellent section on amputations and disarticulations. In the account of Syme's amputation no mention is made of the useful method of dissecting the heel flap from above, a far easier way than dissecting it from below, as Syme described it. It is also advised that in patients under 14 years the posterior epiphysis of the calcaneum should be left in the heel flap; this is certainly not advisable if the amputation is for disease. The illustrations are numerous and for the most part excellent, but in a modern operation the surgeon should not be represented wearing his coat and with his shirt cuffs visible. A useful appendix to this chapter is a brief account of artificial limbs. Dr. Horace J. Whitacre of Cincinnati has written on excisions of bones and joints, and his article is judicious, for he inclines on the whole towards the more conservative procedures. Dr. J. M. Keyes of New York City is responsible for the chapter on the ligature of arteries and veins in their continuity. The account of this branch of surgery is good. It is a pity to speak nowadays of the "descendens noni" nerve, when we recognise 12 pairs of cranial nerves. It should be called "descendens hypoglossi."

The section on minor surgery and bandaging has been contributed by Dr. R. S. Fowler of Brooklyn. The illustrations are specially good and are reproduced from photographs. This chapter includes such matters as exploratory puncture, aspiration, vaccination, and transfusion. Dr. J. S. Stone's article on plastic surgery contains all that can reasonably be expected, and most of the operations described are illustrated. Dr. C. F. Painter of Boston, Massachusetts, has written on congenital dislocations; he preserves a very judicious attitude regarding the treatment of congenital dislocation of the hip, a matter on which many diverse opinions have been expressed. The remaining chapters deal with various departments of orthopædic surgery—Dr. G. D. Stewart of New York writing on torticollis, Dr. C. F. Painter on infantile paralysis, Dr. Royal Whitman of New York on deformities of the lower extremities, and Dr. C. L. Starr of Toronto on caries of the spine. They are all good; we would suggest that it would have been well to point out that "infantile paralysis" by no means rarely occurs in adults.

The whole book, as we have already stated, fully maintains the high standard of the earlier volumes.

Handbuch der Technik und Methodik der Immunitatsforschung (*Hand-book of the Technique and Methods of Investigation of Immunity.*) Edited by Professor Dr. R. KRAUS and Dr. C. LEVADITI. Second Volume, First Part. With one curve and 56 plates. Jena: Gustav Fischer. 1908. Pp. 278. Price 8 marks.

THE study of immunity has enriched therapeutics with curative serums and other substances of the greatest practical value. The technique involved in the investigation of the protective processes summed up under the term of immunity and in the preparation in large quantities of these curative substances is a matter of great importance. The necessity for exact methods and for rigid precautions is, perhaps, greater in bacteriological procedures than in any other branch of biological science. An authoritative textbook by recognised masters of the subject should therefore be of great value, and in the book before us we have an exhaustive and practical description of the methods employed.

Professor R. Kretz of Prague contributes an account of the technique of the preparation of antibodies in large animals, with especial reference to the preparation of diphtheria serum from horses. Dr. Thorvald Madsen of Copenhagen describes the methods of immunisation in small animals. Dr. C. Levaditi, of the Pasteur Institute at Paris, describes the technique of the preparation of antibacterial and antitoxic immune serums as practised in the Institute, more especially in regard to the preparation of diphtheria and tetanus antitoxins, antistreptococcal and antidysenteric serums. The methods for injection of the antigen, for collecting the serum, for preparing and packing it, are described and illustrated. An interesting description is also given of an exsiccator for preparing dried serum. It is capable of dealing with eight litres of serum in eight hours. Dr. Ernst Pribram of Vienna contributes an interesting account of the preparation of antibodies by means of chemical and physical methods. He divides the antibodies into (1) those which hinder a specific effect of the antigen, such as toxic, hæmotoxic, and ferment actions; (2) those which lead to precipitation and agglutination; and (3) those which dissolve cellular structures—"lysins," such as bacteriolysins, cytolysins, and hæmolysins. The effects of various protein precipitants and of various substances obtained from epithelial structures are described. Dr. Thorvald Madsen gives a long account of the properties of diphtheria antitoxin, including the methods for estimation of its antitoxic power and for demonstrating its harmlessness as regards organisms. The nature of the antitoxin unit is explained and the method of its estimation given in detail. The questions of the duration of activity, of the mode of action, and of the prophylactic use of the serum are also discussed in detail. The same author gives a description of botulismus antitoxin. Tetanus antitoxin is discussed by Dr. M. von Eisler and Dr. E. Pribram of Vienna. They give details of its preparation, standardisation, and of its use. They describe the various methods of administration by subcutaneous, intravenous, intraneural, intracerebral, and subdural injection. Dr. R. Doerr of Vienna describes dysentery antitoxin and gives a historical summary of the researches leading up to its recognition as an antitoxic rather than an antibacterial serum. He gives favourable accounts of its action in the treatment of dysentery.

Dr. R. Grassberger and Dr. A. Schattenfroh of Vienna deal with the antitoxin of symptomatic anthrax; and Dr. R. Kraus, also of Vienna, with the antitoxins for the cholera and other vibrios. Dr. R. Stenitzer of Vienna contributes an account of typhoid antitoxins, including those of Chantemesse, Besredka, Macfadyen, and Aronson. Dr. Pribram and Dr. V. K. Russ discuss the various antihæmotoxins. An interesting description is given by Professor A. Calmette of Lille of antitoxins against snake poisons. The problems of natural immunity, of artificial active immunisation, of titration of the immune serums, and of polyvalence are all considered as well as the therapeutic applications of the serums. Professor M. Jacoby of Berlin deals with antibodies for vegetable toxins, including antiricin, antiabrin, and anticrotin; and Dr. O. C. W. Prausnitz of London with hay fever antitoxin. Each article has a useful bibliography attached to it.

This book is a valuable addition to bacteriological literature and should be almost a necessity in bacteriological laboratories.

LIBRARY TABLE.

The Elements of Hygiene for Schools. Compiled by ISOBEL MCISAAC, late Superintendent of the Illinois Training School for Nurses. New York. The Macmillan Company. 1909. Pp. 172. Price 3*s.* 6*d.*—The aim of this book is to present the subject of hygiene in such a way that it may be of practical everyday use to a large number of pupils who will have little opportunity for study of the subject, but it contains a great deal more than could be assimilated by scholars of elementary schools, and is more fitted to the intelligence of the teachers in such schools. In the opening chapter a short account of micro-organisms is given, and chapters follow on general hygiene with reference to air, soil, and water. The dissemination of disease is dealt with, as are also personal, household, and school hygiene, the hygiene of occupation, and the employment of women and children. There are nowadays many little books published containing information of this sort, and Miss McIsaac has produced a good specimen of the class.

A Handbook on Foreign Study. Edinburgh: The Darien Press. Pp. 150. Price 6*d.* net.—This little book contains valuable information concerning the universities of Europe in a form very suitable for reference. Its aim, as stated in the preface, is firstly, to popularise in British academic circles the idea of studying abroad; and secondly, to afford those who desire to study abroad some general guidance as to the best place to go with the maximum of pleasure and profit. The handbook is made the more valuable by reason of the fact that it has been compiled mainly from official publications or reports "based on personal experience." We have for several years published in various Students' Numbers of THE LANCET information regarding post-graduate study abroad, so far as medical education is concerned, but this little book, which has been compiled and edited by Mr. H. J. Darnton-Fraser under the auspices of the Students' Representative Councils of Great Britain and Ireland represented at the British Universities Students' Congress, deals with all the faculties in the universities of Europe. Mr. Haldane, the Secretary of State for War, contributes an introduction, and there are short articles by Professor William Osler on Medicine, Dr. J. Hogarth Pringle on Surgery, Professor Pringle Patterson on Philosophy, Dr. J. A. S. Watson on Agriculture, the Rev. T. W. Watt on Divinity, Dr. T. C. Thomson on Science and Engineering, and some general remarks on the Study of Law. The information in regard to each university town is given under such headings as fees, cost of living, climate, attractions, libraries, museums, vacation courses, and so forth, and a most useful feature is information as to the cost of a journey to any particular town.

The Fourth Olympiad. Drawn up by THEODORE ANDREA COOK. British Olympic Association. Pp. 794.—This is the official report of the Olympic Games celebrated in London in 1908. It deals with the performances of some 20 different nationalities in 20 divisions of sport and records the outcome of more than 100 separate athletic contests, together with the code of rules under which competitions took place in each of these events. It forms, therefore, a sort of blue-book on the conditions and circumstances of athletics at the present day, and as such will have an interest for many of our readers. Among the illustrations are a picture of Queen Alexandra presenting Dorando with a gold cup, reproductions of the medals and prizes won by the several competitors, portraits of the competitors themselves, and pictures of various incidents during the course of the Olympiad.

Woman in Industry, from Seven Points of View. By GERTRUDE M. TUCKWELL, CONSTANCE SMITH, MARY R MACARTHUR, MAY TENNANT, NETTIE ADLER, ADELAIDE M. ANDERSON, and CLEMENTINA BLACK. London: Duckworth and Co. 1908. Pp. 217. Price 2*s.* 6*d.* net.—This series of chapters presents a useful and lucid account of the position of the woman worker, the several writers considering in turn the regulation of work for women, the minimum wage they should accept, and their lot in trade unionism, while other topics such as infant mortality, the employment of children, and factory legislation come in for close attention. The book, which is intended to be read by the general public, has a preface by Mr. D. J. Shackleton, M.P., in which the importance of organisation and the necessity for educating public opinion are equally insisted upon.

The Children of the Poor. By A. D. EDWARDS, M.B., B.S. Lond. London: Hammond, Hammond and Co. 1909. Pp. 74. Price 1*s.* net.——*Wastage of Child Life as exemplified by Conditions in Lancashire.* By J. JOHNSTON, M.D. Edin. London: A. C. Fifield. 1909. Pp. 95. Price 1*s.* net.—The author of "The Children of the Poor," who is medical officer to the Bournemouth Education Committee, has had many opportunities of studying the lives of the children of the poor in the only places where such study can be adequately made—namely, in their own homes. He writes with a sympathetic pen and his sketches of child life in the slums, in the workhouse, and in the hospital bear the stamp of truth. He is unsparing in his condemnation of such things as "soothing" medicines and "teething powders." "For every one child," he says, "who dies as the result of an accidental overdose of these drugs a thousand infants are damaged seriously in constitution," and his reproaches of the law which allows the Government to benefit largely by the sale of such concoctions form the echo of medical opinion that has been expressed over and over again. In almost every continental country children, at any rate, are protected to some extent from these things by legislation, while Australia and the United States are considering strong measures to suppress their sale Realising that the child is the nation's most valuable asset, he concludes his little book with the words: "As evolution tells us that since these children are born and live long years it were better for the State that they should be given during infancy and childhood the chance of health, so economy indicates that the cost of exchanging so many weakly adults for healthy, useful citizens would be a good investment for the State."——Dr. Johnston's book forms No. 7 of the Fabian Socialistic Series, and deals in a systematic manner with the same subject. It also is written out of full knowledge of the subject and forms a useful addition to what must now be becoming a very voluminous literature. But this is as it should be, for the subject is one for the very serious attention of the public mind.

JOURNALS AND MAGAZINES.

The Seventh Bulletin of the Sleeping Sickness Bureau—The monthly bulletins of the Sleeping Sickness Bureau are always valuable as they contain accurate summaries of all the recent papers and publications relating to sleeping sickness and other forms of trypanosomiasis. Bulletin No. 7 is no exception, for it well maintains the high standard attained by its predecessors. Under the heading of Trypanosome Transmission Experiments, a summary is given of Professor Kleine's observations which were published in May last in the *Deutsche Medizinische Wochenschrift.* These experiments were undertaken primarily to ascertain whether infective tsetse flies convey T. gambiense to a healthy animal only once—i.e , mechanically, or if they are able to infect many animals one after the other in the course of several days or weeks. The latter result, if proved, would show that a sexual development of the trypanosome occurred in the fly. Kleine believes that his experiments prove that the transmission of T. gambiense by the glossina palpalis is not mechanical, but that the fly is the true host of the trypanosome. He also concludes that the development of the parasite in the fly may take a shorter time than the 20 days which he had formerly assumed to be the required period. Another interesting abstract is that of a paper by Carlo Chagas of Rio de Janeiro, who describes two new trypanosomes, one of which he found in a marmoset, and the other in a species of bug (conorrhinus) which is present in great numbers in the poorer-class houses in the State of Minas (Brazil), and which frequently bites human beings, particularly children, on the face. Chagas succeeded in finding in the blood of a patient a trypanosome identical with that found in the bug, the inference being that this particular bug is the transmitter of the trypanosome Another summary relates to a number of papers dealing with the factors influencing the incubation period in trypanosomiasis, another discusses the symptoms of human trypanosomiasis We may also mention summaries dealing with lesions of the optic nerve in trypanosomiasis, including atoxyl blindness, the action of human serum on trypanosome infections, the vitality of trypanosomes in cadavers, the bionomics of tsetse flies, the treatment of human and animal trypanosomiasis, and trypanosomes in various animals Appended to the bulletin is a detailed programme of the work which is now being carried out in the Sleeping Sickness Commission's laboratory in Uganda, and which demonstrates the comprehensive character of the investigations Another long and useful list of works of reference on trypanosomiasis, continued from the last number, is given at the conclusion of the bulletin

Man —The July number of *Man* contains a long paper entitled "Notes on the Hair and Eye Colour of 591 Children of School Age in Surrey" It is by Miss Barbara Freire Marreco, and was submitted in compliance with a regulation for the diploma in anthropology in the University of Oxford in June, 1908 The area in which the children lived extended from Chobham to Godalming and Shamley, Guildford being the only town included within its limits The observations were recorded, in the manner recommended by Dr John Beddoe, on a card ruled into three divisions for eye-colour and subdivided into columns for five colours of hair The outstanding feature of the record was the predominance of "medium" eyes—i e, those of a dark bluish grey, hazel, or light brown colour—amounting to 65 per cent for all the children The colour of the hair called by Dr Beddoe "niger" or absolute blackness was not observed among these children Miss Freire Marreco explains the methods employed by Dr Beddoe and by Collignon respectively for computing the numerical inferences to be drawn from such observations, but she thinks that neither of them is satisfactory when there is a large predominance of "medium" eyes with 36 per cent of brown hair

FROM

THE LANCET, *SATURDAY*, August 13th, 1831.

BELLUM MEDICUM AT WARSAW.

To the Editor of THE LANCET

SIR,—It is to be regretted very much that such serious disputes should have arisen at Warsaw amongst the medical staff there, on the subject of cholera It is, I will admit, difficult to discuss scholastic questions without awakening the passions, but when such a devastating demon as this disease is making such fearful strides, it is lamentable to see men quarrelling about bismuth and calomel If they continue their bickerings, I would recommend the aid of a third metallic remedy—lead—to be administered not to the poor patients, but to the doughty doctors, or I would make bottle imps of them, and leave them like their prototype in the *Diable Boiteux*, until some friendly Asmodeus came to release them Two of these gentlemen, I find, are thinking of fighting for the reputation of their panaceæ, and if they kill each other in their chivalrous tournament, they will not probably be missed at the Polish capital Many men have usefully turned their swords into ploughshares, and if these two doctors change their lancets into rapiers, perhaps the Poles will not lose by the transformation

Mais assez de badinage As to remedies for this epidemic, practitioners must depend upon chance more than upon the efficacy of any medicinal agent Any one who has seen many cases of cholera, must know that all our theory and treatment regarding it are sheer speculations, and if he have the candour to confess it he will say that we are absolutely ignorant of its causes and its cure How absurd, then, and empirical does it appear to see two men going to fight for what they conceive the indisputable merits of calomel and bismuth, for the removal of this disease! During a campaign of three years as assistant surgeon in the Indian army, in the worst climates, I never saw a case of cholera cured by any reputed specific It was admitted that the most sensible and rational practice was to meet the symptoms as they presented themselves, and not to adhere to the use of any particular medicine, whatever name or character it might have acquired I could enumerate many ways (but I would not fight for any one of them) of what I might call curing cholera, but I dare not trespass so much upon the pages of your journal I will conclude therefore by saying that I will never believe any man, although armed with bismuth and a broadsword, that he can cure cholera, until he can establish a remedy for it as certain as sulphur for psora, mercury for syphilis, or cinchona for intermittent.

I am, Sirs, yours, &c,

August 8, 1831 VIATOR.

[illegible]

by the Curator of the Royal College of Surgeons in Ireland, the President of the College, and the Professor of Anatomy in the University of Dublin, is open to any student whose name is on the anatomical class list of any school in the United Kingdom In 1910 the prize is offered for a dissection of the cervical sympathetic and preparations entered must be in the hands of the Curator on or before April 30th Particulars of the conditions under which the competition must be carried out and printed forms necessary for application can be obtained from the Curator of the Royal College of Surgeons in Ireland

THE
BRITISH MEDICAL ASSOCIATION.
SEVENTY-SEVENTH ANNUAL MEETING
AT BELFAST.

THE SECTIONS.
OPHTHALMOLOGY.
THURSDAY, JULY 29TH.

President, Dr. J. W. BROWNE (Belfast).

Professor EMILE FUCHS (Vienna) read a paper on

Malformation of the Cornea in Cases of Inherited Syphilis.

He said that the work of Hutchinson gave the first account of the later symptoms of inherited syphilis, and since the time of his writing scarcely anything had been added to our knowledge, so complete had been the initial description. His present paper was a trifling contribution to Hutchinson's work. It had struck him that in some cases of the disease the cornea was shaped as a vertical ellipse. The normal cornea tended to have the appearance of a horizontal ellipse because the tissues of the limbus encroached on the cornea above and below, but this appearance was more apparent than real. In these cases of disease, however, the vertical ellipse was real, and not due to encroachment of the limbus. So far he had not arrived at the cause of the malformation, nor had he enough material, as yet, to say with what frequency it was observed. In 28 cases noted 20 occurred in females, and it was noteworthy that interstitial keratitis was much more frequent in females. Half of the cases had interstitial keratitis, 5 chronic iritis, 1 congenital cataract, 2 corneal opacities, probably the result of strumous keratitis. The remaining 6 were old people with senile cataract. Excluding the last 6 old people, for in age the diagnosis of inherited disease was not readily made, he found that in the other 22 cases 8 showed definite inherited syphilis, 8 some indications of it, and 6 no symptoms. During the year he had seen about 50 cases of fresh interstitial keratitis and only 8 of these had the ellipse, so that it was by no means common. He thought that the malformation might prove to be another of the signs of the inheritance of syphilis, although it must, like other signs, be taken with due regard to other conditions.

Mr. E. TREACHER COLLINS (London) asked if Professor Fuchs had examined any of these oval corneæ anatomically so as to eliminate the possibility of the ellipse being due to encroachment of the limbus. The natural human shape was the horizontal oval, and this was marked in fœtal eyes and in some cases of microphthalmia.

Professor FUCHS replied that he had as yet had no opportunity for anatomical examination. But the vertical ellipse was a striking feature, and with it went marked irregular astigmatism often to as much as 5 to 10 dioptres.

Dr. W. B. INGLIS POLLOCK (Glasgow) read a paper on

The Visual Acuity of School Children.

He said that the statistics of visual acuity found in annual reports of different educational authorities varied greatly. In Scotland they were for some parts as low as 6·5 per cent. defective, in others as high as 77·8 per cent. defective—an amazing difference. The London County Council return for 1,196,504 children during the last two years and nine months was 10·39 per cent. defective. The speaker had come to a percentage of 11·65. In some measure the difference was due to modes of testing vision. In London the best binocular vision was taken as the standard; in other places the vision of the worse eye, in yet others that of the better eye was taken as the basis for statistics. Each claimed merits for its procedure. But he said that the vision of the worse eye was not the vision of the child, neither was that of the better eye so good as a rule as of both eyes acting together. The present haphazard mode of compiling statistics was likely to bring the whole question of medical inspection of school children into contempt and discredit.

Mr. N. BISHOP HARMAN (London) said that he had had a large experience of school eye work in London; that led him to the conclusion that the recent edict of the Board of Education that the vision of each eye of a child must be taken separately caused a futile waste of time. We wanted

odd eyes; that, he thought, was an objection weigh seriously in practice. He had made larg tests and found the alleged error of this mode small as to be negligible. He regretted tha had nothing to tell them of the eye conditio for these defects in vision. Recently he had results of the examination of the eyes of children, with results that were to be found i ings of the Royal Society of Medicine (Section of Disease in Children), May, 1909. The myopia in school children was no more than and probably less, for their tests caught the n those hypermetropes who had good accommoda

Dr. R. WALLACE HENRY (Leicester) thou elimination of cases of odd eyes was necessa the headache caused by such a condition. H Mr. Harman's returns of the incidence of myo he had examined all the defective in 10,000 ch the total only 2·5 per cent. had myopia. In rate of increase of myopia it was necessar the age factor, and not the relation to cla for myopes were handicapped and tended to standards.

Professor R. A. REEVE (Toronto) questio quency of asthenopia in children; it mostly ca age of from 20 to 30 years, and he found th not suffer in school years.

Dr. A. FREELAND FERGUS (Glasgow) read a

Trephining in Glaucoma.

He said that his operation was essentially a Lagrange's operation. He had no hesitation his modification stood or fell with that of Lagr tomy was difficult of performance, but treph tremely easy. He turned forwards a large con then with a Bowman's corneal trephine bored of the sclera as close to the limbus as possi slipped a repositor between the sclera and th until the point of it appeared in the anterior c conjunctiva was replaced and the operation It had the advantage of being so little painful anæsthetic was quite unnecessary, a point of gre since the subjects of chronic glaucoma were suffering from vascular disease and took gener badly. Again, there was no risk of injury to t lastly, the risks of sepsis could be reduced to a the large conjunctival flap speedily adhered an wound. Trephining the sclera had been perfor by Argyll Robertson, but he cut the sclera far did it for the temporary relief of tension. further said that he advocated the method for only, since the regular iridectomy was by f treatment for acute cases. He gave details o securing asepsis of the conjunctiva.

Dr. A. HILL GRIFFITHS (Manchester) comm Fergus's methods of examining the flora of th previous to operating. He agreed that it w thought that in any case it was not possibl membrane from organisms.

Dr. A. LITTLE (Bradford) remembered Arg doing his early operations. His own objection tion lay in the risk of subsequent infection of th the thin conjunctiva overlying the gap in th was sure a cystoid scar increased the risks of th in some cases he had seen hypopyon iritis y operation.

Mr. G. A. BERRY (Edinburgh) said that any in be considered from the point of view of glauco Dr. Fergus aimed at a filtration cicatrix. of opinion that iridectomy was the best a cedure, and he should not do any other operat had been tried and failed. In his hands irid very rarely. He believed that success in irid removing a piece of healthy iris. If a cystoid he should say that the glaucoma process h checked.

Mr. TREACHER COLLINS said that Dr. Fer operations: (1) sclerotomy; and (2) cyclodialysis made of the repositor must detach the ligar tinatum and so put the anterior chamber steps in the operation Dr. Fergus attributed his success. In his own experience cystoid scars were not a permanent success, but he had had some good results with cyclodialysis.

Mr. S. **JOHNSON TAYLOR** (Norwich) asked if the method had been tried on blind, painful, glaucomatous eyes; if it could save enucleation then it had a distinct value.

Mr. **THOMSON HENDERSON** (Nottingham) agreed that permanent bulging wounds indicated that the glaucomatous process had not been checked by the operative procedure.

Professor **FUCHS** said that he had trephined, but had given it up. Further, he had had experience of cyclodialysis and his assista [illegible] hopefu [illegible] to say t [illegible] that the amelioration was not permanent; the tension recurred, and anatomical examination of some of these eyes showed that the scarring of the tissues at the seat of the operation was very dense, so that the passage of the aqueous was less in these parts than elsewhere around the filtration angle. He put iridectomy first as the operation for choice.

Dr. **FERGUS**, in reply, said that the elimination of organisms from the conjunctiva could not be obtained by the use of drugs. What he did was to irrigate the conjunctiva with plenty of sterile normal saline solution several times a day for four days prior to operation when time permitted. That the result was worth the trouble was proved by the fact that in 700 cataract extractions he had not lost one by suppuration. He agreed that iridectomy was the operation for choice, but there were cases of the chronic order in which some form of sclerotomy seemed of value.

Mr. **TREACHER COLLINS** (London) opened a discussion on

Disease of the Lymphoid Tissue of the Conjunctiva.

He said that trachoma was the particular disease to be discussed. He had exceptional opportunity of studying it in the schools of the Metropolitan Asylums Board. Children found to exhibit eye trouble in London Poor-law schools were drafted into these isolation schools until free from disease. In the past five years he had received 2441 patients, and of these 700 were suffering from trachoma. Many of them exhibited the disease in its earliest form. The first point he wished to emphasise was that trachoma was a contagious disease. When first one of these schools was started a "house mother" and a nurse, both previously healthy, contracted the disease in an acute form from an affected child. Again, the schools were so delightful in their surroundings that children were loath to leave, and he had found that some admitted for simple disorders deliberately inoculated themselves with discharges from their fellow pupils' eyes; in these cases of inoculation, as definite as any possible, trachoma resulted. The contagious character of trachoma being established, there could be little doubt that the contagious element was a micro-organism. He then referred to the work of Prowazek and Greeff, who, working independently, had discovered in cells from trachomatous tissues by the use of Giemsa's stain minute ovoid bodies smaller than the smallest known cocci. The evidence in favour of their being a specific organism lay at present in the frequency of their appearance in trachoma and their absence in other diseases. In any case they could be sure that the contagion was not air-borne, but that it was conveyed in discharges. For if ordinary precautions of cleanliness were taken neither nurses nor medical men in constant attendance on these cases became affected. Next, there was no doubt that the disease was unlike purulent and muco-purulent inflammations of the conjunctiva, for in these the process was limited to the epithelial lining. Trachoma was more like tubercle, in that both alike produced definite endothelial nodules which were the essence of the diseases. It would therefore seem likely that the contagion of trachoma would be found to exist most commonly in the lymphoid tissues. That the trachoma bodies of Prowazek and Greeff were found only in epithelial cells seemed to him to tell against their being the specific organism. The earliest symptom of the disease appeared to be the presence of grey, scattered, avascular spots, rather smaller than a pin's head, in the tarsal conjunctiva of the upper lid. Graefe and Jacobson had termed these "elementary or primary granulations." Their presence might be obscured when there was coexisting catarrh. The trachoma organism would appear to be non-pyogenic; its toxin seemed to cause immense new formation of lymphoid tissue, increase of plasma cells, and in the later stages formation of fibroblasts. Mayou had pointed out that the characteristic discharge of trachoma was an enormous number of plasma cells. Trachoma was essentially a chronic disease; acute symptoms were usually the result of intercurrent infections—the Koch-Weeks bacillus in England, or that and the gonococcus in Egypt. In the process of cure the follicles might disperse naturally by rupture. They might be absorbed, particularly when there was invasion of polynuclear leucocytes, such as was fostered by intercurrent catarrhal affections and by most of the modes of medical treatment. Gross fibrosis such as was obvious to the naked eye was not a necessary end to the disease; with the best results the scarring might be so minute as to be invisible to the eye. As regards treatment, expression of overloaded follicles by squeezing them out, and excision of the retrotarsal folds in the exceptionally bad cases, were both useful procedures. Mr. Collins never found complete excision of the folds and tarsus necessary. The time-honoured copper sulphate still held first place as the best application to stimulate absorption of the follicles He referred to Leber's experiments with different metals inserted into the anterior chamber as explanatory of the action of copper salts. Kataphoresis of copper had been tried, but it was too painful. Jequiritol was of much help in obstinate cases. X rays were painless but variable in their results, probably because of the difficulty in securing exact dosage. Radium he had used with little result, for the quantity at his disposal was not very active. Grattage, the stimulation of the tissues by violently rubbing them with hard brushes, spiked iron instruments, or the knife blade, acted only by stimulating the growth of scar tissue. He concluded by stating that in his experience trachoma was completely curable, though the process was long.

Professor **RICHARD GREEFF** (Berlin) followed, and gave a description of his investigations into the bacteriology of the disease. For the last 10 to 15 years numerous workers had laboured indefatigably at the subject, and it was only when new methods of staining were discovered that his hopes of a real advance had been raised. In Giemsa's stain they had a reagent that had a remarkably selective action on all protozoal material. In collaboration with his assistant Dr. Clausen, and later with Professor Frosch, he had made extensive investigations on both trachomatous and non-trachomatous disease. The bodies which he had found were extremely minute. They were found for the most part massed together in pairs or clusters near the cell nucleus, in the form of a cap, only separated from the nucleus by a narrow clear margin. The space containing the granules enlarged rapidly, causing the cell to swell and burst. They were found most frequently in the epithelial cells, but they had been seen in the deeper adenoid tissues. They disappeared on treatment. So far they had not been cultivated. The bodies had now been recognised by many workers in different parts of Europe and even in Japan. They differed essentially from the granules of eosinophile cell débris. He thought they were more akin to protozoa than bacteria.

Mr. A. F. **MACCALLAN** (Cairo) described the work being organised under his direction in Egypt in the formation of ophthalmic hospitals for the treatment of trachoma. One fully equipped hospital had been built at the cost of £7000 at Tanta, another would be completed shortly at Assiout, and a third was in course of erection at Mansoura at the expense of an Egyptian gentleman. The travelling hospitals were doing excellent work. Of the extent of the spread of trachoma amongst the population no better evidence could be given than the condition of one primary school in which 96·43 per cent. of the pupils showed active or passive trachoma. He next dealt with the phases that the disease presented during its existence and progress towards cure.

Professor **FUCHS** said that he had tried to find these new trachoma bodies and had succeeded; indeed, he had been able by this mode of staining to differentiate doubtful cases [illegible] this was a [illegible] epithelium [illegible] tissues or [illegible]

Mr. **SYDNEY STEPHENSON** (London) said that in early days there was much confusion, owing to the teaching that the presence of follicles in the conjunctiva was an early stage of trachoma. That this was not true could be shown by the examination of the children of the general population. After seeing some 15,000 children of varied classes he concluded that only 5 per cent. had conjunctivæ free from changes of some sort or other. Folliculosis was closely associated with such conditions as adenoids and enlarged tonsils. Follicles in the conjunctiva were not the first stage of trachoma, but had an entirely different significance. The cases of inoculation described by Mr. Collins, and many he had seen himself, left no doubt in his mind that trachoma was not an air-borne, but an essentially contagious disease. Further, he was convinced *that proper segregation and treatment would secure* extermination of the disease.

Mr. JAMES A. CRAIG (Belfast) said that Ireland enjoyed the unenviable position of being classed next to Egypt as a country in which trachoma was rife. Unfortunately this was true of the industrial schools and workhouses: they were hotbeds of infection. And all this was due to lack of the most ordinary precautions of cleanliness and hygiene. Legislation was badly wanted. The disease was worse than small-pox, for the sufferer was contagious indefinitely. He cited an instance where five nurses were infected with acute trachoma. As regards treatment, he could say that cure had been obtained in from six to nine months in selected cases—that is, in patients who were healthy generally and whose surroundings were good. He no longer held with "bold" surgical methods and brass had banished wire brushes; they did more harm than good. Copper sulphate was ahead of anything else.

FIG. 1.

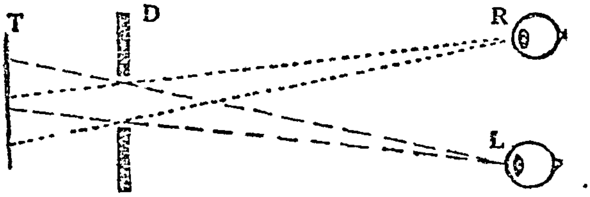

FIG. 2.

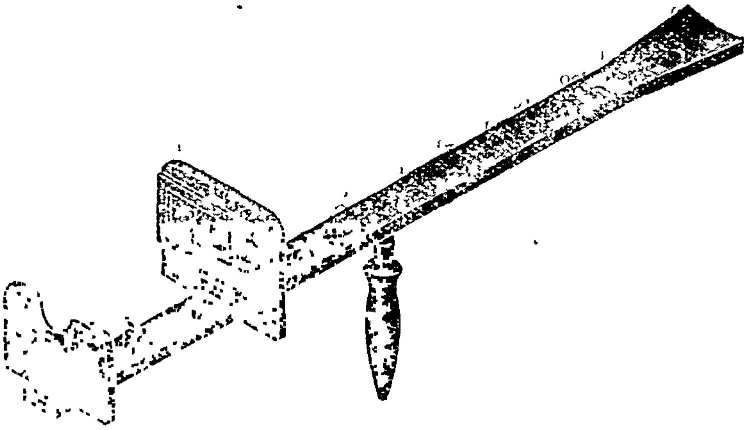


Dr. JOSEPH NELSON (Belfast) contrasted the results of treatment of two school outbreaks. In one, ordinary drug treatment was used and the disease spread. In the other, a separate colony was formed, good food and good hygiene were obtained, and these measures with drug treatment stayed the plague. He said it was desirable that the common people should know of the disease and get a "holy horror" of it, then it would be checked.

Dr BYERS (Toronto) and Professor REEVE (Toronto) spoke of the work that was done by emigration authorities for the prevention of the entry of diseased subjects into new countries.

The executive of the section was asked to draw up a resolution on the necessity for Government "*action*" in the suppression of the disease.

FRIDAY, JULY 30TH.

The executive of the section, following the recommendation arrived at in the discussion on Trachoma on the preceding day, presented a resolution for the acceptance of the section to the effect that the Government should be urged to institute measures for the checking of the spread of the disease. After considerable discussion, a resolution, drawn up and proposed by Mr. TREACHER COLLINS (London), and seconded by Dr. A. GREENE (Norwich), was put to and accepted by the meeting:—

> That the Council of the British Medical Association be asked to draw the attention of the Local Government Boards of the United Kingdom to the pr lower classes, to the damage to sight contagious character of the discharg and to the importance of preventing any transference of such discharge from one person's eyes to another's by means of the washing appliances in the institutions under their control.

Mr. J. H TOMLINSON (Egham) demonstrated the usage of a new instrument of his invention,

A Skotograph with Binocular Fixation.

The instrument could be used as a perimeter, particularly for the mapping out of blind or anæsthetic areas. The test object used to prove the sensitiveness of the retina is a second image of the spot of light used as the fixation point. The second image is obtained by reflection from a mirror *hinged within a cone, the angle of the mirror determining* the angular position of the second image on the retina The cone could be rotated round its axis so that the second image is caused *to make a circular excursion on the retina*. In this way Bjerrum's method of investigation can be employed. The instrument automatically registers the subjective findings of the patient on suitable charts.

Dr. ALEXANDER FLEMING (London) gave a demonstration of his modification of the

Wassermann Serum Diagnosis for Syphilis,

an account of which was published in THE LANCET of May 29th, 1909, p. 1512.

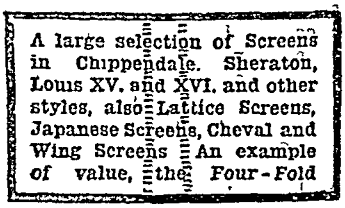
Mr. LESLIE PATON (London) said that Dr. Fleming had examined by these means many of his eye patients at St. Mary's Hospital, and the results were surprisingly good and useful.

Mr. N. BISHOP HARMAN (London), in the course of a demonstration of the

"Diaphragm Test" for Binocular Vision and its Disorders,

said: This test is one of extreme simplicity, and yet one that will elicit a surprising amount of information when applied in practice. It is simple because it rests upon a phenomenon that is of every-day occurrence. On looking out of a window the man who has natural binocular vision sees more widely than does the man who has but one eye or who sees with but one eye at a time. With this test the patient looks through a hole in a screen (D, Fig. 1) at the test-card (T) The paths of the vision are shown in Fig. 1, and the manner in which right and left monocular and also binocular vision is arranged for. The form of the instrument is shown in Fig. 2. The appearance of a test-card for reading is seen in Fig. 3; the dotted lines on the print enclose the band of print seen by both eyes; the lateral portions are seen by each eye singly by crossed vision. The test-cards are of great diversity. Print of any size from diamond in set paragraphs to canon in paired capitals; black or coloured squares variously disposed; pictures for children. The test is of value for the following purposes: (1) To determine the equality of visual acuity in the two eyes; (2) to determine the presence, the absence, or a defect of binocular vision; (3) to exercise the vision in squinting eyes; (4) to detect malingerers feigning monocular blindness; and (5) to demonstrate certain physiological phenomena. Take, for example, latent squint: the phenomena produced

FIG. 3.



A large selection of Screens
in Chippendale. Sheraton,
Louis XV. and XVI. and other
styles, also Lattice Screens,
Japanese Screens, Cheval and
Wing Screens An example
of value, the Four-Fold

123456789

The man with good binocular vision reads 1234 with the right eye, 6789 with the left, and 5 with both eyes. In convergence (esophoria) the middle letters are overlapped and are suppressed so that the man reads something like this:

126789

In divergence (exophoria) the middle letter is reduplicated, and the man reads:

12345 56789

In vertical displacement (hyperphoria) the parts of the line of letters seen by each eye are on different lines or levels, thus:

12345
56789

All these phenomena can be seen by the surgeon himself when an excessive prism is placed before one eye, or by simply displacing one eye by the push of the finger. Again, a malingerer can hardly escape detection by the use of this test. Answers by the mouth are not necessary, for the surgeon, watching the man's eyes, will see *the coordinate movements of the eyes as the man looks from one to other area of crossed vision.* The movement is proof of two-eyed vision; the man with only one seeing eye does not make it. Mr. Harman continued that in recent experiments with the instrument he had found that by varying the size of the hole in the screen it was possible to estimate numerically the value of the desire for perfect binocular vision, or what is known as the "fusion faculty." The instrument is well and cheaply made by Messrs. George Culver, Limited, of White Lion-street, London, N.

Dr. **Inglis Pollock** said that he found the diaphragm test of the greatest use in examining patients for reading glasses. It took only a minute to tell whether or no the patient had equal vision in the two eyes and whether binocular vision was present.

Professor **Fuchs** considered the instrument to afford a very good and simple test.

The section then united with the Section of Obstetrics and Gynæcology, and with Dr. **John Campbell** in the chair proceeded to examine the

Report of the Ophthalmia Neonatorum Committee.[1]

In presenting the report Mr. **Sydney Stephenson**, chairman of the committee, said that the committee was a responsible one; it represented many interests. Some of their recommendations were of a far-reaching character and had therefore been referred to the divisions. In this joint discussion their business was recommendation to the Council, not final acceptance of the report.

Dr. **Wendell Reber** (Philadelphia) said there were phases of the subject that appealed greatly to him. In the United States they had benefited greatly by the strenuous work done by Lucien Howe. It struck him that there was a tendency to take the matter out of the control of medical men. This was a danger to be guarded against, particularly in England where so much work was done by midwives. These should not be permitted to use Credé's prophylaxis; in the United States this could only be used by the medical man. Again, they had got much benefit by removing both mother and affected child to the hospital; a child should not be cut off from its proper food at such a critical time. It might seem far-fetched but it was not impossible that the mother who had suffered a vaginitis elaborated within her blood an antitoxin that was beneficial to the child.

Dr. **George Carpenter** (London) spoke as a children's specialist, and pointed out that the loss to the child who was the victim of the disease was not only that of sight but of [illegible] greed that there should be [illegible] And he did not believe [illegible] is. Their only hope was compulsory notification and immediate treatment.

Dr. **A. Nimmo Walker** (Liverpool) objected to the universal teaching of Credé's method by obstetricians. The method was not an absolute protection and it sometimes caused permanent damage. There was a reduction in the incidence of the disease and that was not due to Credé's method but to Listerian cleanliness. He questioned the where diagnosis was uncertain. At the St. Paul's Hospital they had had great success in treatment by taking into hospital both mother and child. Further, their methods had become known to midwives who had learned to send to them infants of suspected mothers, so they could absolutely forestall the onset of the disease.

Dr. **Wallace Henry** said what general practitioners wanted was a definition of ophthalmia neonatorum; without some clear definition notification was impossible.

Mr. **Bishop Harman** said that the report was excellent in its general features. But to get any real success in their efforts after legislation or the application of existing legislation they must create a public feeling on the matter. Government officers and ministers would not take any steps *in advance of public demands, they had to be forced to work*, for independent action only brought them into difficulties. They had been in some degree successful in arousing opinion. Only last year at the International Congress of the Blind in Manchester the subject came up for discussion, with the result that a committee of members of the different blind societies and colleges of the kingdom met and, with the help [illegible] mittee were county councillors and they had exerted useful influence on their colleagues. By such means we could do much. [illegible] difficult [illegible] tion of [illegible] Society made years ago was ample for all purposes: "If the child's eyes become red and swollen and begin to run with matter ......'" Nothing could be more explicit than that. All these cases should be notifiable. Then the bacteriologist of the local authority would examine films and say whether the case was dangerous or not.

Dr. **J. Wharton** (Manchester) said that in his city they had instituted a voluntary system of notification; there had been no difficulties, and its success had been great. Cases had diminished by 40 per cent. and not one eye of those affected had been lost.

Dr. **R. C. Buist** (Dundee) said that notification was like a net—it fished up much that was not wanted, but it was the only means of getting what they did want. Would they give up notification of scarlet fever because some cases were erroneously diagnosed? A few mistakes were balanced by the immensity of the protection afforded to the public.

Dr. **J. H. Taylor** (Salford) entered a protest against the Association issuing a report that was really an attempt to crystallise treatment. Such a thing was fatal to all progress, and it had a futher serious danger in that such a report would be held in the courts of law to represent the opinion of the 22,000 members of the Association. If a man did not use their treatment, but some he thought better, he would run the risk of charge of malpraxis.

Dr. **Cecil Shaw** (Belfast) said that the objections put forward against the notification of ophthalmia neonatorum were just those that had at one time been put forward in the case of diphtheria. The suggestions for treatment given in the report were not prescriptions but only suggestions. He joined in the protest against the haphazard and unrestricted use of strong antiseptics. Recently he had investigated an outbreak of what was thought to be ophthalmia neonatorum; examination of the discharges showed no organisms, and he was convinced that the whole trouble was the result of the abuse of strong perchloride solutions.

Dr. **J. Staveley Dick** (Manchester) said that there should be as *little dogmatism in medical treatment as possible*, and that therefore the suggestions to practitioners were objectionable. Besides the directions were neither Credé's nor scientific in point of accuracy. He moved an amendment that all that part of page 3 of the report that dealt with "suggestions to practitioners" be omitted.

Dr. **Adam Fulton** (Nottingham) seconded the amendment. He objected to the suggestions to practitioners (1) because they were loose and conflicting; (2) because they recommended a proprietary preparation; (3) because they implied that general practitioners were quite ignorant of how to treat such cases. It was a gratuitous assumption of superiority.

---

[1] We publish this report on p. 477 of the present issue.

Dr. HENRY said that solicitors' opinion was to the effect that adoption of the suggestions to practitioners would clothe them with almost binding authority in the eyes of the law.

Dr. R. J. JOHNSTONE (Belfast) said the suggestions, if adopted, would only reach those who were already familiar with the subject and not those who might need teaching.

The amendment was put and carried; the motion for the acceptance of the report, so amended, was carried unanimously.

The meeting closed with votes of thanks to the Presidents of the two sections.

TROPICAL MEDICINE.

WEDNESDAY, JULY 28TH.

President, Dr. C. W. DANIELS (London).

The PRESIDENT opened a discussion on

The Persistence of the Tropical Diseases of Man due to Protozoa

by stating that the persistence of the protozoal infection of a single host had to be carefully distinguished from the persistence of protozoa in general. The latter depended on the complex life-history of the parasite, including its sexual development; the former, as far as was known, depended on the length of time during which asexual multiplication could take place without requiring rejuvenescence by sexual reproduction. The great increases in our knowledge of protozoa all pointed in one direction—namely, to an alternation of processes of multiplication, sexual and asexual. In many this was conclusively proved. Dr. Daniels exemplified these processes in the cases of malaria, coccidia, in amœbæ and intestinal flagellates, in spirochætæ and in trypanosomes. In all these cases the disease-causing period of the life of the protozoa was the period when the asexual reproduction was taking place. The sexual forms were harmful, because they were the usual agents in the transmission of disease from one warm-blooded host to others. It was to the sexual development that the peculiar distribution of many tropical diseases was due, but as regards the individual host the sexual reproduction might be ignored. They were therefore limited in that discussion to the consideration of protozoa in their asexual stages. More details of structure of the protozoa must be made out, however, before they could understand many unexplained observations as regards chromatin transformations, especially in the trypanosomes. They were induced to consider sexual reproduction as the ordinary method of multiplication and the asexual as something phenomenal and exceptional, whereas the exceptional reproduction was the sexual, and for long periods only the asexual form occurred. Dr. Daniels illustrated these phenomena and took as an example the proteosoma in birds. In this case they started with infection by parasites which had been rejuvenated by sexual reproduction. An interval of some days took place before any parasites were found in the bird and then only in small numbers; a rapid increase occurred, so that in three or four days after their first appearance 10 or more parasites might be seen in a one-twelfth field. Should the bird survive this, the infection steadily but slowly diminished, and in two or three weeks the parasites again became scanty and the bird recovered. Subsequently parasites might be found in small numbers, but might ultimately permanently disappear. Any parasites seen appeared normal with an average number of spores. The parasites did not increase in number, showing that some influence was at work which, while not arresting the normal multiplication of the individual parasites, caused the destruction of the greater majority of the parasites as they were formed. This influence was not present in the bird when first infected. The phenomenon above referred to might, on the other hand, be explained by assuming that the virility of the parasites became lessened owing to prolonged asexual reproduction. Against this explanation, however, they had the observation that if the blood of the infected bird, whilst but a few parasites were found, was injected into a healthy bird infection resulted, and the same sequence of gradual increase, diminution, and persistence would obtain. Were, again, the blood of the second bird injected into a third a similar phenomenon would ensue, and by the inoculation of a succession of birds proteosoma might be maintained for years without any alternation of sexual reproduction or alteration in the characters of the parasites, showing that it was owing to changes in the host, not to loss of virility of the parasite, that subsidence and disappearance of infection were due. In malaria in man the same series of events occurred, but for how long infection of malaria continued was not yet determined. Blood examination alone could solve the question and more observations were required. In some cases one year in a non-malarial country would see the end of parasites, but in others three years might pass and still malaria parasites might be found in the blood. That this natural cure might be due either to loss of virility in the parasites from repeated asexual reproduction or to a marked increase in the natural resistance and formation of antibodies might be doubted. It was probable that the protective agencies originated and maintained by the parasites themselves were directly concerned in this phenomenon, and should these fail, which might or might not happen, there was no reason against absolute permanency of an infection. The President referred to the development of strains of protozoa differing in their resistance to hostile agencies, and cited as an example strains of Trypanosoma gambiense which proved resistant to atoxyl. The resistance and destruction of the protozoa were, as in bacteria, in the main an affair of alterations in the host, and the time taken varied with different protozoa as it did with different bacteria and with the same bacteria in different hosts. There would appear to be an essential similarity of protozoal infections multiplying asexually and bacterial infections, and in considering protozoa they were prone to lose sight of this fact and to disregard the principles that guide them in bacterial diseases. It must not be forgotten that in countries where reinfection was frequent persons after four years' continuous residence showed a steadily diminishing tendency to become reinfected, whilst after 10 years it was exceptional to find anyone who could be reinfected, showing that a condition inimical to the parasite had been established. That this condition was not a permanent one was proved by the fact that by residence in a non-malarial country where reinfection was not possible, this immunity was lost and reinfection occurred when return was made to a malarial district. After referring to the want of any natural resistance in man to the malaria parasite, and the possibility of intestinal parasites multiplying asexually by fission in the intestine, and throwing off encysted forms which appeared to represent an attempt at a sexual phase, the President concluded by stating that it would be a sounder view to consider protozoa as causes of disease as more on a par with bacteria, and, as with them, to use our efforts to increase the resistance of man to these parasites as well as to endeavour to destroy the parasite.

Dr. A. BREINL (Liverpool) related a case of recurrence of malaria in a patient in which microscopical examinations confirmed the diagnosis after an interval of seven years. The recurrence was coincident with an attack of acute appendicitis. In trypanosomiasis, he said, experimental work showed that after apparent freedom from trypanosomes for even four months artificially induced illness in a monkey caused a reappearance of the parasite in the blood. Dr. Breinl hesitated to compare closely bacteria and protozoa, as the President suggested, and he was convinced that though asexual multiplication might go on for an indefinite period, resistant forms might develop which escape the destructive action of "antibodies" but which after the disappearance of the antibodies resume an asexual multiplication.

Dr. J. L. MAXWELL (Formosa) referred to the difficulty of settling the question of persistence of infection of malaria owing to asexual multiplication in a country where re-infections were possible as in almost all tropical countries. It was therefore in countries such as Great Britain that the matter must be studied.

Mr. JAMES CANTLIE (London) drew attention to the persistence of malaria infection in his own person for three years after returning from the tropics and residing in London. During the hot months of July and August he had persistent fever. During the corresponding period of the fourth year a severe attack of neuritis in the left upper limb seemed to replace the febrile periods of previous years. Drugs had no effect in cutting short the neuritis, and it was only by improving the general health of the host by work in the harvest field that the malaria infection seemed to be destroyed. Mr. Cantlie advocated residence in a cold, dry climate as that best suited to get rid of malaria infection speedily.

Major J. K. RITCHIE, R.A.M.C., considered that in the elucidation of tropical diseases generally they had to look to the physiological chemist rather than to the bacteriologist for information. He believed that change to a cold climate was the best method of getting rid of malaria.

Dr. C. A. STONE (Dooars, India) pointed out that in certain cases of malaria, especially malignant tertian, quinine failed and he questioned whether quinine acted directly on the parasite or in a more roundabout way.

Mr. J. STUART BROOKE (Allahabad, India) considered that residence in a cold climate was the best means of treating persons infected with malaria.

Dr. O. E. MCCUTCHEON (Assam, India) said that by mosquito nets and quinine man could be protected from malaria, but there were many difficulties in the way, especially in the case of children and newcomers to the tropics. I[illegible] with attacks of fever every [illegible] was most unsatisfactory. [illegible]

A Short Study of the Pathology of the Blood in "Verruga."

Fleet-Surgeon P. W. BASSETT-SMITH, R.N. (Haslar Hospital), having received a number of blood films taken from two acute cases of "verruga" in Lima, Peru, gave a minute description of his findings. He described verruga as an infectious inoculable disease of very limited geographical distribution, being endemic in certain valleys in the western slope of the Andes. From its prevalence in the Oroya district it was sometimes spoken of as Oroya fever. The disease was ushered in with fever, the patient complained of gastric pain and cramps; there were swelling of the joints, enlargement of the spleen, and anæmia. After a time, it might be one month to one year from the initial febrile attack, the characteristic granulations appeared on the skin, the mucous membrane, and the internal viscera. The disease attacked men of all colour, and was fatal to the extent of from 10 to 40 per cent. of those attacked. Isquierdo had described a long headed bacillus as being common in the morbid growths and adjacent vessels. The films examined by Fleet-Surgeon Bassett-Smith showed an intense anæmia with an extraordinary abundance of nucleated red cells and a relatively high leucocytosis. No large protozoal organisms were seen in the blood. The red cells showed variations in size and shape, great irregularity of staining; very large and very small red cells showed most chromatic changes. Nucleated red cells were remarkably abundant, with great variation in the character of the nucleus; double and treble nuclei were common, quatrefoils and cinquefoils were seen, as well as rosette-like appearances. A true mytosis of the nucleus was also seen. Besides the meta-chromatism and the basophilic granules in the cytoplasm there were seen in many cells minute rod-like bodies, frequently showing as diplococci from the intense staining of the ends, or as beading from two or more lying end to end; occasionally small, deeply stained rings or pyriform bodies were made out, but no red chromatin spots. It was not certain that these appearances were due to degeneration of the protoplasm, as they differed from the ordinary basophilic granules of anæmic blood; they suggested extraneous pathological bodies causative of the degeneration. The symptoms of verruga, *its limited distribution, specific* nature, and profound blood alterations made it probable that the cause might be an intra-corpuscular organism very minute and difficult to stain.

OBSTETRICS AND GYNÆCOLOGY.

THURSDAY, JULY 29TH.

President, Dr. JOHN CAMPBELL (Belfast).

Dr. E. HASTINGS TWEEDY (Master of the Rotunda, Dublin) initiated a discussion on

Endometritis.

He said that he made the following divisions of the disease: clinically, acute and chronic; anatomically, corporeal and cervical. Acute *endometritis* was always of microbic origin. It might [illegible] diseases of [illegible] metritis. [illegible] proceed on general principles, dead areas of infection should be removed and pus pools drained, and the general bodily resistance should be increased. Before douching a specimen of the discharge should be taken for bacteriological examination and the preparation of a vaccine. Ante- and retroflexion should be remedied. The blunt curette was occasionally useful, especially when there had been repair of the perineum which might be injured by passing the hand. The sharp curette was useless and harmful; it opened up fresh avenues of infection and there was great danger of perforation. The symptoms of chronic endometritis were menstrual disturbances, amenorrhœa, dysmenorrhœa, menorrhagia, passage of clots and casts. Referred symptoms were pain in the back, weakness in the loins, weariness on slight exertion, headache, and dyspepsia. Curetting was the method of treatment in all cases, and in doing it he advised preliminary dilatation. After applying the curette he washed out with a Bozemann's catheter and then swabbed with 1 in 3 formalin on a Playfair's probe, taking care to boil the probe after putting on the cotton wool. He put in a wick of gauze which was retained 24 hours. He kept the patient one week in bed. Mild cases might be treated without curetting by swabbing with 1 in 3 formalin or by the injection of iodine, but he would not do the latter oftener than once in three months, and he deprecated the frequent applications of some gynæcologists. No operation for the repair of the perineum or cervix or for displacement of the uterus should be done without a preliminary curetting. For cervical endometritis he advised partial amputation of the cervix or dilatation of the canal and light application of the cautery. Cases of severe hæmorrhage which could not be cured by curetting were best treated by atmocausis, and he had seen no harm result from that treatment.

Professor J. FEHLING (Strasburg) said that he would separate entirely acute endometritis due to gonorrhœa from the other forms. In treating chronic endometritis he would first separate the cases which were due to general disease and which required no local treatment. He thought in some cases the symptoms were due to narrowing of the cervix brought about by over-zealous cauterisation. He advised the wearing of a flexible intra-uterine tube after dilatation or curetting. He was opposed to frequent cauterisation. In performing curettage it was most important first to ascertain the length of the uterus by the sound and to keep the external hand on the fundus while passing the dilator. He had given up atmocausis. He would not amputate the cervix in fertile women. He treated erosion by the application of the sharp spoon.

Dr. ARCHIBALD DONALD (Manchester) said that there were *many varieties of endometritis*; the most typical form occurred in connexion with mild septic infection after abortion, but cases arose in unmarried women independently of pregnancy or gonorrhœa. In the puerperal case the fundus was large and retroflexed, and these cases were treated on wrong lines by pessaries and plastic operations, curetting being the essential factor in the treatment. The symptoms of endometritis were hæmorrhage, leucorrhœa, dysmenorrhœa, and dragging in the iliac region and hypogastrium. He believed strongly in gauze packing after curetting. As regards erosion, he thought that in the majority of cases it was due to an irritating discharge from the corporeal endometrium; he would treat it by curetting, but in much-thickened cervices he would remove a wedge-shaped piece.

Dr. F. W. KIDD (Dublin) thought that when the cervical canal was inflamed they always found the endometrium to be affected. He had known cases in which permanent amenorrhœa had followed the too vigorous application of the curette.

Dr. F. J. MCCANN (London) said that he combined curetting with a modified rest cure lasting from four to six weeks. He used a blunt curette for the body and a sharp one for the cervix, and [illegible] 50 per cent. chloride of [illegible] te puerperal endometritis [illegible] s to wipe out the uterus.

Dr. THOMAS WILSON (Birmingham) considered that the only indication for curetting was hæmorrhage, and that it was useless for pain or discharge. He found that in all cases in which the cervix was dilated to above No. 13 Hegar, laceration at the internal os occurred. After curetting he applied strong iodine fortnightly for three months.

Dr. THOMAS CULLEN (Baltimore, U.S.A.) said that during four years he had all the uterine scrapings which had been removed in a large hospital practice examined by a pathologist, and in only 48 cases was there evidence of endometritis. From the histological standpoint there was no difficulty in the diagnosis, but clinically it was often impossible to say whether endometritis was present. Uterine discharge was often due to a general systemic weakness, and it disappeared when attention was paid to the general health. He used bladed dilators.

Dr. Alfred Smith (Dublin) said that in puerperal septic endometritis he used the finger and the curette after abortion. He used no intra-uterine treatment in the gonorrhœal form. To prevent laceration he performed a preliminary dilatation by tent.

Dr. Henry Jellett (Dublin) said that he used formalin. He had seen occlusion of the cervical canal after the use of chloride of zinc. He agreed that curetting should accompany plastic operations for retroflexion, and he combined it with Alexander's operation for moveable retroflexion, and ventral fixation when the uterus was adherent.

Dr. F. Edge (Birmingham) dwelt on the advantages of hollow Hegar's dilators, which prevented any possibility of pushing fluid up into the tubes.

Dr. Samuel J. Cameron (Glasgow) said that the most difficult cases to cure were those of gonorrhœal origin, and in these it was unwise to curette.

Dr. Alexander W. Russell (Glasgow) urged the importance of sexual rest in cases of endometritis.

Dr. T. B. Grimsdale (Liverpool) agreed with Dr. Donald that endometritis was the most important factor in cases of retroflexion.

Dr. J. Munro Kerr (Glasgow) had found with Dr. Cullen that in many cases regarded clinically as endometritis little change could be found when the endometrium was examined histologically. Cases in which curetting failed often were really cases of metritis.

Professor Henry Corby (Cork) said that he used bladed dilators, and thought the special value of gauze packing was that it stimulated the uterus to contract.

Dr. E. J. MacLean (Cardiff) thought that lacerations began when Hegar's dilators above No. 9 were used. He had found that cases in which packing was used did not have so easy and afebrile recovery as when a pack was not put in.

The President said that it was impossible to clear out the puerperal uterus by the finger. He used the sharp curette for curetting.

Dr. Hastings Tweedy, in reply, said that he would draw no distinction between acute endometritis due to gonorrhœa and that due to other forms. He used gauze wrung out of 2 per cent. carbolic acid for packing.

Dr. Louise McIlroy (Glasgow) gave a lantern illustration of a series of slides showing

The Development of the Epithelial Elements of the Ovary.

The investigations which they illustrated extended over some months and were assisted by a grant from the British Medical Association. The ovaries used were from human embryos as well as from those of the puppy, kitten, and pig. The speaker claimed to have proved that the so-called Pflüger's tubules were really Graafian follicles with a hollow centre due to the ovum being at a different level or having dropped out. She pointed out that many of the cells in the stroma bore a marked resemblance to those of chorion-epithelioma. She considered that the rabbit's ovary, which was often used, was inferior for research to those of the animals she had investigated.

Dr. David Waterston (Edinburgh) discussed the paper.

Dr. Smallwood Savage (Birmingham) read a paper on

An Ovarian Tumour Clinically Malignant Arising from the Overgrowth of Lutein Cells.

He said that there were three cases of such tumours on record and gave references and particulars. In his case the patient was 38 years of age, a widow and the mother of four children. Menstruation had been regular up to three months before, since when there had been slight irregular losses. There had been pain and loss of flesh for seven weeks. The patient lived five and a half months after operation. The specimen consisted of the right ovary enlarged to the size of a fœtal head. Microscopically some cells were degenerated and vesicular; the nucleus was pushed to the side; the whole structure strongly resembled that of the corpus luteum. The tumour was undoubtedly malignant, the patient dying from cachexia, but without evidence of local recurrence. There was no post-mortem examination.

Professor Fehling said that he had found that in a case of this kind there was a history of hydatid mole.

Dr. Munro Kerr thought that in all cases of malignant disease of the ovaries the uterus should be removed.

Mr. H. T. Hicks (Derby) alluded to the association with hydatid mole.

Dr. Louise McIlroy and Dr. Edge also contributed to the discussion.

Friday, July 30th.

Professor Fehling (Strasburg) read a paper on

The Treatment of Cases of Contracted Pelvis.

He said that the earliest prophylactic treatment was induction of premature labour as advised by Denman. He mentioned special feeding, designed to reduce the size of the child, as suggested by Prochownik, and said that experiments on animals had confirmed Prochownik's views. The putting on of fat took place in the last six or eight weeks of pregnancy, and the dieting would be more likely to have effect if applied then. The second way of obtaining a small fœtus was by the induction of premature labour, and this was especially useful in the simple flat pelvis. He would only use it in multiparæ. He generally induced labour between the 35th and 37th week by using hydrostatic dilators, seeking to obtain cephalic presentations as far as possible. The fœtal mortality in his clinic had been 24 per cent. Walcher's position gave an increase of the conjugate of 1 to 1·5 centimetres, and he had used it successfully in cases of after-coming head. The best means, however, of increasing the available space was by pubiotomy; this gave, with a space between the bones of 4 to 6 centimetres, an increase in the conjugate of ½ to 2 centimetres. For cases in private practice he advised high forceps, and even in some cases perforation of the living child when required in the interest of the mother, but in the clinic if the child's life showed signs of danger he chose Cæsarean section. As regards the technique of pubiotomy, he used Doederlein's or Bumm's; in the former the needle was passed from above downwards, a small incision being first made in the skin; in the latter the needle was entered from below between the labium minor and majus; in each case the Gigli wire saw was used, and the needle was guided by a finger in the vagina. He awaited spontaneous labour after dividing the bone, placed a tampon in the vagina for 24 hours, and kept in a self-retaining catheter for 48 hours. His maternal mortality has been 3·2 per cent. and the fœtal mortality 9·6 per cent. He preferred pubiotomy to symphysiotomy, as the latter gave rise to more bleeding and was more likely to be attended by damage to the urethra and bladder, and he had used pubiotomy after inducing labour if the head became impacted. He mentioned the newer method of extra-peritoneal Cæsarean section, in which, after the abdominal incision, the peritoneum was stripped up off the lower uterine segment; he preferred the longitudinal incision and did not think it mattered if the peritoneum was accidentally opened if the opening was at once closed. The operation must be done when the lower segment was well stretched, and was not suitable for the early stage of labour.

Professor Murdoch Cameron (Glasgow) said that pubiotomy left permanent lameness, and he preferred induction of labour by bougies.

Dr. Munro Kerr had not found induction of labour satisfactory, and the fœtal mortality from high forceps in his hospital had been 50 per cent. He emphasised the great importance of leaving cases to nature as long as possible, and he had seen spontaneous labour with a conjugate of 3 inches. He thought pubiotomy extremely valuable and that it was especially indicated in cases where one thorough attempt at forceps delivery had proved unsuccessful. Pubiotomy was very undesirable in primiparæ, and there were cases in which it was justifiable to perforate the living child, especially when the genital canal was infected.

The Master of the Rotunda said that the pelvis was often inaccurately measured. There was only one reliable means of measurement, and that was Skutsch's pelvimeter, which required an anæsthetic. In serious contraction Cæsarean section was the only operation possible, but it must not be forgotten that the uterine scar might be a source of subsequent danger. They should act when the fœtal heart were still some cases in which perforation of the living child would be justifiable in private practice.

Professor **Fehling**, in reply, found that patients could walk perfectly well after pubiotomy even when there was failure of bony union. He measured the pelvis with fingers under anæsthesia.

Professor **Murdoch Cameron** read a paper on

Cases of Dystocia due to Ventral Fixation of the Uterus.

He narrated two cases; in each the os was high up and could only be reached by introducing the whole hand into
to be treated by embryotomy.
ses in which ventral fixation was

down on the anterior wall to prevent such an accident.

ANATOMY AND PHYSIOLOGY.

Wednesday, July 28th.

President, Professor C. S. **Sherrington** (Liverpool).

The **President** gave a brief introductory address, in the course of which he referred with regret to the absence of Professor Symington. He said that it had been decided to hold a joint meeting of anatomists and physiologists this year, and in view of this the officials of the section had sought for discussion subjects which might be discussed by the mixed audience, from both the structural and functional points of view.

Professor A. F. **Dixon** (Dublin) then read a paper on

The Anatomy of the Achondroplasic Skeleton.

This was illustrated by lantern slides, photographs, and dried bones. Professor Dixon referred in particular to two adult

did not escape. *Of the former, those bones which began to* ossify early were most affected. Hence deformities were very marked in the long bones, while short bones, as those of the carpus and tarsus, showed very little abnormality indeed. Further, the amount of deformity in the different parts of a long bone bore some relation to the relatively early times at which ossification appeared in them. Thus the shaft of a long bone was the seat of chief deformity in it; the epiphyses were but little different from normal. The striking changes found in long bones were these. The shafts were markedly shortened and thick, while the ends were almost normal in size. The natural curves were exaggerated; muscular markings were unusually prominent. In the skull the base was found to be much contracted, especially in an antero-posterior direction, while the membranous part of the cranium, actually very little affected, appeared by contrast

into the cranial cavity, so that the foramen magnum was about on a level with the external auditory openings. The foramina in the skull base were abnormally small. The different angles of the base were much changed. The clivus, the most contracted part of the base, presented an unduly steep slope. A variable amount of ankylosis between the skull and the atlas was found, although no obvious limitation of nodding movement might have been observed during life. Professor Dixon, in speaking of achondroplasia as particularly affecting bones ossified in cartilage, drew attention to the fact that he had found the clavicles to be practically unaffected. Indeed, in one case clavicle and radius were of the same length.

Professor C. J. **Patten** *(Sheffield) asked as to Professor* Dixon's experience of an absence of symmetry between corresponding bones of opposite sides in cases of achondroplasia.

described the changes in shape found in these and compared them with those found in achondroplasia. He remarked upon the absence of change in growth in the case of the vertebral column, coupled with great changes in the skull in the achondroplasic skeleton, and asked whether Professor Dixon had found associated changes in the genital glands,

had met
d shapes
resembling achondroplasic skulls, and asked as to any
ctions, or between achondro-

at about 17 to 21 *years of*
predominate.

Dr. N. C. **Rutherford** (Edinburgh) asked how the membrane bones of the face were affected, and spoke anent the alleged connexion between the pituitary body and achondroplasic changes.

Professor **Peter Thompson** (London) also spoke of the condition of the hypophysis and its possible effect on growth.

The **President** remarked upon the greatly developed markings for muscular attachments in some bones shown by Professor Dixon. He would expect them to be marked in some proportion to the duration of the muscular strain upon them, and hence would look to find them prominent in the case of postural muscles, such as were attached to the femora.

Professor **Dixon**, replying, said he had deliberately confined his paper to cases exhibiting symmetrical deformities. In the two cases described he had not recognised any changes in the genital glands. The brain showed a slight degree of hydrocephalus. The cranial capacity was very variable. The membrane bones of the face were slightly affected and the entire face seemed to be pushed back underneath the cranium. He had not found microscopic changes in the pituitary body. The cancellous tissue resembled that of normal bone. The condition of achondroplasia was found in families, but was probably not inherited through the female line.

Dr. Robert H. **Scanes Spicer** (London) read a paper on

Some Points in the Mechanics of Respiration.

For the convenient illustration of some of his remarks he showed a rough model representing the larynx and vertebral column, *showing alterations in shape and relations of* these parts during respiration. Costal and abdominal types of respiration were described and compared, the latter being condemned as bad. It prevented proper voice-production and was chiefly responsible for voice troubles in singers and speakers and tended to impair health. Different views had been held as to the movement by which the vocal cords were stretched. Dr. Scanes Spicer held that this was a movement of the cricoid cartilage upon the thyroid and not *vice versâ*. Respiration involved strains upon different parts of the larynx. These were in a degree limited or neutralised by movements occurring around the transverse crico-thyroid axis, and hence its importance. In proper breathing (costal type) the larynx practically, he thought, made no excursion up and down, and the vertebral column tended to straighten itself out. In abdominal breathing, especially if deep, the *vertebral column behind the larynx had its forward convexity* increased, the larynx underwent an up-and-down excursion, and at the same time was so tilted around its transverse axis that the cricoid cartilage projected backward. The bosses on the back of this, uncovered by muscle, were brought unduly against the vertebral column, and by their movement (as parts of the larynx) up and down over the sharp points and ridges on the front of the column a mild but long-continued frictional irritation was kept up, which probably played a part in determining the incidence of cancer in this situation.

Professor **Thompson** declined to regard the model as correctly representing the movements occurring in nature. It was easy to move a model and to say, "This is what occurs." It
orrect.
He objecte
upon
abdominal
s but
normal, and agreed with Professor Keith's views. It was the type which obtained in quiet breathing, as in sleep. Costal respiration came markedly into play when an extra effort

was required. The diaphragm took part in both types; it descended and it raised the lower ribs. He knew of no bony points on the vertebral column such as Dr. Scanes Spicer mentioned. In the recent state the front of the column was made smooth by the anterior common ligament and other soft tissues.

Questions were asked and remarks were made by the PRESIDENT, Dr. J. S. DICKEY (Belfast), Dr. RUTHERFORD, and Dr. WATERSTON as to the effect of costal respiration on laryngeal movements, the relative frequency of throat cancer in the two sexes, and in relation to pregnancy in view of the prevailing types of respiration involved.

Dr. SCANES SPICER, in reply, recommended the use of the terms "belly-breathing" and "back-breathing" instead of abdominal (diaphragmatic) and costal. Back-breathing was the right type and should be cultivated. He quoted Sir Felix Semon's figures as to the frequency of throat cancer in the two sexes.

Dr. HUGH MACLEAN (Liverpool), in a paper on

Phosphatides,

indicated how little was definitely known of these bodies. Widely distributed, he said that they existed in all tissues, especially such active tissues as brain and heart, and they could be extracted by suitable agents—e.g., ether. They were nitrogenised, phosphorised fatty acids, of the rôle of which in metabolism but little was known. They were very oxidisable, and acted as aggravators of hæmolytic poisons. They occurred in yelk of egg in variable quantities. For experimental purposes he obtained three grammes of phosphatides in an ethereal extract of 100 hen's eggs. With this he made many experiments to ascertain the chemical structure and relations of phosphatides. As a result, he concluded that they probably played an important part in the normal desaturation of fatty acids in the body. They could be divided into various groups according to the proportions of nitrogen and phosphorus present. Of the first group, in which the proportions of nitrogen and phosphorus were as 1 to 1, lecithin was the best-known example. Of many of the groups practically nothing was known. Dr. Maclean was unable to determine in detail the nitrogen combinations in phosphatides. His observations, however, satisfied him that the generally accepted formula of the phosphatides' chemical structure could not be taken as entirely correct.

Dr. REID HUNT (Washington, U S.A.) described experiments which he had made upon the phosphatides to ascertain their chemical structure.

Professor B. MOORE (Liverpool) mentioned hypotheses as to the different composition of phosphatides and referred to their effects upon blood pressure and metabolism.

Professor T. H. MILROY (Belfast) made a few remarks.

There was general agreement as to the slightness of knowledge about phosphatides and the width of the field which they offered for further research.

PATHOLOGY.

THURSDAY, JULY 29TH.

President, Professor W. ST. CLAIR SYMMERS (Belfast).

The section was joined with the Section of Hæmatology and Vaccine Therapy for a discussion on "The Early Diagnosis and Treatment of Pulmonary Tuberculosis." We report this debate under the proceedings of the latter section.

FRIDAY, JULY 30TH.

Dr. A. E. MOORE (Cork), Vice-President of the section, took the chair, whilst the President of the section read a paper by Dr. L. COBBETT (Cambridge) on

The Portals of Entry of Tubercle Bacilli into the Body in the Causation of Phthisis.

Dr. Cobbett said that the object of his experiments was to find out (1) whether bacteria could gain entrance to the lungs directly through the air passages; and (2) whether, after being absorbed from some part of the alimentary canal, they could pass at once through the lymphatic glands and gain entrance to the lungs. The general intention of the experiments was to throw light on the question of the portals of entry of the tubercle bacilli into the human body in the causation of phthisis. The experiments were divisible into three groups—namely, those made (1) with particles of carbon; (2) with bacillus prodigiosus; and (3) with bacillus tuberculosis. The animals used were guinea-pigs, except in a few instances, in which rabbits and mice were employed. The results might be briefly summarised as follows: (1) Feeding experiments with particles of carbon (25 experiments). (*a*) Young guinea-pigs fed with Indian ink or lamp-black on one or more occasions showed no pigmentation of mesenteric or cervical lymphatic glands, and no pigmentation of lungs or bronchial glands, except in two experiments, when the conditions were such as did not exclude the possibility of the pigment being inhaled directly into the lungs. (*b*) Feeding adult guinea-pigs in a similar manner resulted in no pigmentation of the mesenteric or cervical glands nor of the lungs or bronchial glands; such pigmentation as was found in these latter situations in some of the guinea-pigs fed with carbon being equalled in other animals of corresponding age which served as controls, as some degree of pigmentation of lungs and bronchial glands in normal guinea-pigs of 500 grammes and over was found to be common in Cambridge. The results of these experiments were directly opposed to the belief that pigmentation of the lungs was of intestinal origin, and suggested the possibility that spontaneous pigmentation might sometimes have been mistaken for the result of an experimental feeding with carbon. (2) Experiments with bacillus prodigiosus. (*a*) Cultures were made from a large number of organs and glands of 26 animals exposed to a spray containing the bacillus In all the more recent experiments the spray used was of the finest description, and was continued only for one or a few minutes. It scarcely sufficed to produce any perceptible wetting of the coats of the animals. Bacillus prodigiosus was cultivated from the extreme marginal portions of the lung of all these animals in which the interval between spraying and death did not exceed 15 hours. In two instances the animals ceased to breathe within three and five minutes respectively of the commencement of the exposure to the spray. The bacillus did not fail to reach the lungs after the œsophagus had been ligatured in two places and divided. The bacillus reached the bronchial glands in ten hours, if not earlier, but was not found in them after the fifteenth hour. It was twice found in the mesenteric glands and once in the cervical. It was invariably absent from other parts of the body, except in the case of one of the earlier animals, which was entirely exceptional. (*b*) 14 guinea-pigs were made to swallow large quantities of bacillus prodigiosus, they were killed after intervals of from 3 to 14 hours, and cultures were made from their organs and glands. In the case of about half the guinea-pigs one or two colonies appeared in one or more of the four tubes sown copiously with lung emulsion. It was, however, by no means certain that these reached the lungs after being absorbed from some part of the alimentary canal, for it seemed probable that the bacilli did not survive long enough in the stomach and intestines to do so—only rarely could a colony of bacillus prodigiosus be cultivated from their contents; and in not one of these experiments did bacillus prodigiosus appear in the cultures from the mesenteric glands. Once, however, a single colony appeared in a tube sown from the submental gland. Observing the frequency with which guinea-pigs make a choking noise when feeding, and especially when fed artificially, there was no difficulty in believing that the bacilli in question had reached the lungs directly by the air passages. Intertracheal injections of small quantities of these bacilli were followed by their appearance in the margins of the lungs. (3) Experiments with bacillus tuberculosis. 13 feeding and 14 inhalation experiments were undertaken. The former were by no means complete. The results were, on the whole, similar to those obtained after feeding with bacillus prodigiosus, and their interpretation awaited further experiments. When guinea-pigs were fed with tubercle bacilli and allowed to live some weeks tuberculosis appeared first in the mesenteric or cervical lymph glands and no disease appeared in the lungs until it became generalised elsewhere. The spraying experiments clearly showed that tubercle bacilli suspended in the air could readily penetrate deeply into the lungs. When the animals exposed to the spray were killed a few minutes or hours after and their emulsified organs injected into other guinea-pigs tuberculosis was invariably produced by the lung emulsions. A much less severe tuberculosis was in some cases produced by the bronchial or mesenteric glands. When guinea-pigs exposed to the spray of tubercle bacilli were allowed to live from one week to a month and then killed and examined tubercle bacilli were found in large numbers in the lungs before any lesions appeared anywhere. Elsewhere they were absent, except in small numbers in the bronchial and cervical lymph glands. Tuberculous lesions first appeared in the lungs, then in the bronchial glands, after which they were found in the portal lymph gland and the spleen. The mesenteric glands invariably escaped tuberculosis, but in one case (out of ten) three tubercle bacilli were seen 14 days after exposure to the spray. In conclusion, Dr. Cobbett said that the experiments as a whole were not yet completed, but they clearly showed already that in the guinea-pig bacilli suspended in the air readily passed down the bronchi deeply into the lungs. The experiments were not sufficiently advanced to justify any conclusions as to the course of infection which followed the introduction of tubercle bacilli into the alimentary canal.

The PRESIDENT pointed out that Dr. Cobbett had obtained results diametrically opposed to those yielded by the experiments of himself and Sir William Whitla, and consequently the final conclusions of Dr. Cobbett would be awaited with great interest by those who maintained, like himself, that food and not air was the usual vehicle of the tuberculous virus.

Dr. W. FORD ROBERTSON (Edinburgh) and Dr. MARGARET C. W. YOUNG (Edinburgh) presented their observations made in connexion with

The Protozoal Origin of Tumours.

The communication resolved itself into a demonstration of three distinct series of lantern slides; the first giving schematic representations of the life cycles of hæmamœba and other parasitic protozoa, contrasted and compared with the hypothetical life cycle of Robertson's silver-cyanide protozoon (for which the name "neucloamœba" was suggested). The second demonstrated the cyanide-fast bodies observed in Jensen's mouse tumours, and the third similar bodies found in cancer cells in the human subject—these last two series being arranged to demonstrate appearances and phases in agreement with stages in the hypothetical life cycle of the authors' micro-organsim. A comprehensive series of water-colour drawings of the microscopical appearance described by the authors, and several microscopical sections were exhibited in an adjoining room.

Dr. J. M. BERNSTEIN (London) pointed out that in the early stages of the study of pathogenic protozoa, silver-staining methods were deemed essential for their demonstration, but that subsequently it was found possible to avoid the fallacies introduced by silver methods by employing the eosin methylene-blue compound devised by Romanowski and its various modifications, such as Leishman's. He inquired whether Dr. Robertson's protozoa could be demonstrated by these stains.

Dr. ROBERTSON explained that his bodies could only be satisfactorily shown by the special silver process which he used, and in which all the fallacious appearances inseparable from other silver processes were eliminated.

Professor E. J. MCWEENEY (Dublin) read a paper on

The Value of Coloured Substrata for the Detection and Differentiation of Members of the Typho-coli Group.

The speaker said that in view of the great epidemiological importance of typhoid carrier cases and of the etiological relationship of non-lactose-fermenting bacilli of the Gaertner group to outbreaks of meat poisoning, any method which would admit of the speedy recognition of such organisms on our culture plates would constitute a welcome addition to bacteriological technique. There were two ways of accomplishing the desired object—viz., by substrata, which should either (1) cause the bacteria which do not ferment lactose (typhoid, paratyphoid, dysentery) to assume a distinctive appearance, or (2) suppress as completely as possible the growth of the ordinary lactose fermenting coli organisms, so as to allow the relatively few non-lactose fermenters to appear prominently on the plate. The methods are not mutually exclusive and may be combined in the same medium. In order to test the relative values of the several methods that had [illegible]

or nearly so, coli bright red), but which did not suppress the growth of coli. 3. A modification of No. 2 by Gaehtgens, which consisted in adding caffeine, a substance known to inhibit bacillus coli. 4. Conradi's new picric acid brilliant green agar. 5. A modification of this by Colonel H. B. Fawcus, described in the *Journal of the Royal Army Medical Corps*, and consisting essentially in the addition of lactose and bile-salt with a less strongly acid reaction. 6. China green agar—viz., an ordinary 3 per cent. agar neutralised to + 13 on Eyre's scale, with 1·4 to 1·5 cubic centimetres of a 0·2 per cent. solution of China green (Grübler) added to each 100 cubic centimetres contained in a flask. This colouring matter was introduced into bacteriology by Werbitzki in the *Archiv für Hygiene* for this year. The speaker exhibited two series of cultures on 6-inch Petri plates on each of these media. One series was inoculated with the fæces of a typhoid case [illegible] same age and the same amount of stool was used for each. The most satisfactory results were obtained with the China green agar, which suppressed about 75 per cent. of the coli colonies, whilst the survivors were much inhibited in their growth, remaining small, opaque, and point-like. The typhoid colonies, on the other hand, developed most luxuriantly and were decidedly more numerous than on any of the other media. Their appearance, moreover, was very characteristic, being of a delicate transparent green, deeper in the centre, with a thin filmy peripheral layer that spread out like a veil over the substratum and presented under a low power a typically sulcate appearance. The only obvious drawback to this medium was the fact that the motility of the bacilli taken from these typhoid colonies was much diminished and they presented a filamentous aspect. Subcultures in broth, however, were in all respects typical by the next day and could be subjected to the usual agglutination and other tests. Next to the China green in point of value came the Conradi brilliant green picric acid medium, which admitted of unrestricted growth of typhoid organisms whilst largely restricting that of bacillus coli. The distinction, moreover, was fairly well marked, the coli colonies being of an opaque greenish-yellow, whilst those of typhoid were more transparent, colourless, larger, and thinner. Their motility and agglutinability were preserved. The speaker's experience of the Fawcus modification being founded on the results obtained from a single batch of medium was not large enough to enable him to make a positive statement as to its value. So far, however, he had noticed that together with a very decided inhibition of bacillus coli the typhoid colonies also were to some extent interfered with, and did not assume definitely marked character until 48 hours had elapsed after inoculation. Nor did they seem so numerous as on the China green. The presence of a cloudy appearance around the coli colonies did not appear to possess any marked advantage, as there was little danger of mistake. As to the original Drigalski and Endo media it was unnecessary for him to speak, as the results were such as might have been expected. On both, the coli colonies occupied the plates to such an extent as to leave little room for the development of typhoid, unless indeed the latter were pretty numerously represented. It was interesting to observe that the Endo medium permitted the growth of large numbers of yeast colonies which did not come up on any of the other media. With a view to demonstrate the appearances of the several members of the group on these media in pure cultivation, he had prepared and now demonstrated a series of plates inoculated with bacilli typhosus, coli, lactis aerogenes, paratyphoid B and A, the speaker's strain of Gaertner's bacillus from the Limerick food-poisoning case, Ratin's and the Flexner and Shiga types of dysentery. The inhibition bacillus of coli was strikingly evident on the Conradi, Fawcus, and China green media, and it was interesting to observe that the two dysentery types were equally repressed. There was no distinction between the Gaertner and Ratin organisms, both of which grew luxuriantly on all the media. In view of the unsatisfactory nature of our present methods of isolating typhoid bacilli from suspected milk, he had been experimenting by infecting milk in quantities of 100 cubic centimetres with typhoid fæces known to contain the bacilli, adding the same amount of China green solution as proved suitable for plate cultures (1·5 cubic centimetres of a 0·2 per cent. solution), and setting aside at 37° to develop for 24 hours, and then plating out on Drigalski's and Endo's media. So far, however, he had not succeeded in obtaining typhoid enrichment in this way. He concluded by recommending China green to the attention of those interested in this class of work.

Dr. Moore then vacated the chair in favour of Professor McWeeney, and

Professor BENJAMIN MOORE (Liverpool) and Dr. W. R. STENHOUSE (Liverpool) described the results of their experiments on

The Growth of the Bacillus of Tuberculosis and other Micro-organisms in Increased Percentages of Oxygen.

In the course of their work they had encountered many difficulties owing to the gradual escape of oxygen from the apparatus in which their culture tubes were exposed. Finally, by placing the cultivations in a glass dish and inverting over them a bell jar, sinking its mouth into a ring of putty, and then filling up the space between the wall of the bell jar and the wall of the containing glass dish with mercury, they were able to maintain an atmosphere of pure oxygen for a considerable period. 37 organisms in all were investigated as to their rate of growth in atmospheres containing varying percentages of oxygen, and of these three species—viz., bacillus tuberculosis, bacillus pestis, and staphylococcus pyogenes aureus—were completely inhibited in their growth. The remaining 34 species differed in no respect from the control cultivations grown under ordinary atmospheric conditions.

Dr. W. S. LAZARUS-BARLOW (London) then occupied the chair and commented upon the fact that of 28 species of bacteria which he had investigated with reference to radio-activity two only—bacillus tuberculosis and staphylococcus pyogenes aureus—had exhibited radio-active properties when placed in contact with the photographic plate, bacillus pestis being absent from the series he examined.

Dr. W. J. WILSON (Belfast) read a paper on

Heterologous Agglutinins, more particularly those Present in the Blood Serum of Cerebro-spinal Fever and Typhus Fever Cases.

His results confirmed and extended observations previously made by Professor Symmers and himself in regard to the agglutination of organisms of the typhoid, colon, and alcaligenes groups by the blood serum of cerebro-spinal fever cases. These heterologous agglutinins are not removed from the blood serum on saturation of the latter with the infecting micro-organism (i.e., the meningococcus), and on this account must be distinguished from group agglutinins (Pfaundler) and mitagglutinins (Wassermann). The heterologous agglutinins increase during the disease and their course of development follows closely that of the meningococcal agglutinins, though to this rule there are many exceptions. They may still be evident in a very high dilution of the serum—e.g., 1 in 2000. The blood serum of a horse which had been immunised against the meningococcus was much richer than normal horse serum in agglutinins, not only for the meningococcus but also for the bacillus aquatilis alcaligenes. Of 31 specimens of serum taken from Belfast cases of typhus fever and examined as to their action on the bacillus typhosus 18 gave a positive and 13 a negative reaction with a 1 in 50 dilution of the serum. Seven cases of typhus fever had five times the agglutinative power of normal serum on a variant form of the bacillus coli communis which had been isolated from the fæces of one of the cases.

After some remarks on this communication by Dr. LAZARUS-BARLOW and Professor MCWEENEY had been replied to by Dr. WILSON, a paper detailing the results of studies upon

The Etiology of Bacillary Dysentery

was communicated by Dr. MARC ARMAND RUFFER (Alexandria) and Mr. J. GRAHAM WILLMORE (Gabel El Tor). The material for their investigations had been derived from Mussulmans landed at El Tor during the pilgrimage season and amounted to many hundreds of cases. Etiologically considered, these cases belonged to two distinct groups—amœbic dysentery (due to infection with amœba histolytica alone or in association with a bacillus provisionally designated bacillus dysentericus "El Tor No. 1") and bacillary dysentery. Of this latter group Dr. Ruffer and Mr. Willmore recognised five types, according to the organism apparently concerned in the infection: (*a*) bacillus dysenteriæ of Shiga-Kruse type (comparatively rare); (*b*) bacillus pseudo-dysentericus "D" of Kruse; (*c*) bacillus dysenteriæ of Flexner (one case only); (*d*) bacillus dysentericus El Tor No. 1; (*e*) bacilli resembling but not identical with [illegible] monest type of dysente[illegible] that due to bacillus dys[illegible] could not be distinguished by clinical signs or post-mortem appearances from cases due to bacillus dysenteriæ of Shiga-Kruse, and the diagnosis depended entirely on the isolation of the bacillus or on the result of agglutination experiments, as those cases agglutinated bacillus El Tor but not the Shiga-Kruse bacillus. The diagnosis was exceedingly important, as treatment with the Shiga Kruse antiserum was useless, although this serum was of extreme value in cases of dysentery due to the Shiga-Kruse bacillus. Dr. Ruffer and Mr. Willmore devoted themselves to a most complete and careful study of its cultural, biochemical, and pathogenic characters. The various serum reactions, agglutination, absorption, and complement deviation of bacillus El Tor were next detailed, from which it appeared that it was most nearly allied with Kruse's bacillus pseudo-dysenteriæ D.

Professor MCWEENEY complimented Mr. Willmore on the care and completeness with which he had studied the various forms of bacillary dysentery. The outcome of this work seemed to be that as the result of the complex relations that existed between the intestine and its flora an indefinite number of inter-connected bacillary races or sub-species were evolved. Some of the more commonly occurring of these had been isolated and studied under the names of Shiga, Flexner, pseudo-dysentery, bacillus El Tor No. 1, and so forth, but these were, in his opinion, certainly linked together by an unbroken chain of intermediate forms, and it was only by painstaking studies, such as that brought forward by Mr. Willmore, that the links which were now missing from the chain would be supplied.

The work of the section was then declared at an end in a short valedictory address by Dr. LAZARUS-BARLOW.

DERMATOLOGY AND ELECTRO-THERAPEUTICS.

THURSDAY, JULY 29TH.

President, Dr. W. CALWELL (Belfast).

The following cases were exhibited:—By the PRESIDENT: (1) Adenoma Sebaceum; and (2) Pityriasis Rubra Pilaris. By Mr. G. L. ST. GEORGE (Lisburn) and Dr. G. MONCRIEFF MELVILLE (Youghal): Acanthosis Nigricans. By Dr. S. W. ALLWORTHY (Belfast): Cutaneous Actinomycosis. By Dr. J. CAMPBELL RANKIN (Belfast): (1) Xeroderma Pigmentosum; (2) Lupus Vulgaris, showing result of a plastic operation on the nose; (3) Epithelioma of the Wrist and Senile Keratosis of the Face. By Dr. F. MCLIESH (Belfast): Lupus Vulgaris, of short duration, with ectropion.

A large number of excellent casts and photographs of skin diseases were exhibited in the Pathological Museum by Dr. G. G. STOPFORD TAYLOR (Liverpool) and Dr. R. W. MACKENNA (Liverpool).

Sir MALCOLM MORRIS (London) then opened a discussion on

Mucous Membrane Lesions in Cutaneous Disease.

He said that affections of the mucous membranes might be considered under the headings of (1) primary and (2) secondary. The latter group could be subdivided into (*a*) cases in which the mucous membranes were affected independently of the skin; (*b*) cases in which they were affected by extension from the skin. Having briefly referred to the specific fevers, in all of which the mucous membranes were involved, he enumerated the various drugs—arsenic, chloral, belladonna, mercury, salicylates, iodides, and others—in which lesions occurred in the mucous membranes. Among general infections, syphilis imitated almost every form of disease, and characteristic lesions were found in the mucous surfaces in the primary and secondary stages of the disease. Leucoplakia was an independent disease and not [illegible] in origin. In lupus vulgaris the startin[illegible]e; in 70 to 80 per cent. of Fins[illegible] of the mouth or nose were [illegible] the [illegible] applica- diagnosis of lupus of the [illegible], the tion of adrenalin, as suggested by Dr. St. Clair [illegible] blanching of the mucous membrane causing the lupus nodules to stand out clearly. Lupus might extend up the lacrymal

-duct, the pharynx and larynx might be involved, and the tympanic membrane might be affected through the Eustachian tube. Lupus of the tongue was very rare. Sir Malcolm Morris had seen a case in which the vagina and os uteri were the sites of lupus. It was now thought probable that leprosy tended to show itself first in the nose and pharynx. He had recently had a case of early anæsthetic leprosy in which an ulcer was found in the left nostril, and bacteriological examination showed the presence of acid-fast bacilli in large numbers. Leprous nodules might form in the conjunctiva, or the tongue might be affected with lesions resembling syphilis. In anæsthetic leprosy the mucous membrane of the palate and other [illegible] As regarded skin diseases proper, [illegible] from intestinal toxæmia; erythema [illegible]ered in by congestion of the throat and pharynx. In urticaria, the eyelids, lips, mouth, tongue, glottis, and vulva might be the sites of wheals. Urticaria might alternate or be concurrent with asthma. In urticaria pigmentosa the mouth might be affected. Pemphigus often attacked the mouth or mucous membrane of the bronchial tubes, but Sir Malcolm Morris could not confirm the statement that pemphigus vulgaris might begin in the mouth. In pemphigus foliaceus, however, the mouth, or labia majora or minora might be the first parts attacked. Dermatitis herpetiformis was sometimes accompanied by lesions in the mouth or vagina, and the speaker had published a case in which lesions first occurred on the tongue (water-colour drawings illustrating these and other cases were shown). In epidermolysis bullosa bullæ might form on the mouth and lips, and in each of three children in a family observed by the speaker there were lesions in the mucous membrane of the mouth, whilst in one the intestinal tract was affected. He had recently seen a case of this disease with a well-developed bulla in the mouth, probably caused by eating toast, and he had also had a case in a patient, aged 60 years, which had been called pemphigus by the late Sir William Gull. Catarrhal herpes affected the lips, tongue, and genital organs; it was often the result of external irritation. Herpes zoster might attack the eyeball, and vesicles were occasionally seen on the tongue. Eczema might spread to mucous membranes. The red part of the lips might be involved in seborrhœic eczema and become covered with crusts. Lupus erythematosus inside the lips and cheeks often resembled leucoplakia or lichen planus. The conjunctivæ and larynx were occasionally affected, and Wilfred Warde held that rhinitis and lesions of other mucous membranes were often associated with lupus erythematosus. Lichen planus was not infrequently seen on the tongue and inside the mouth and often resembled leucoplakia. These lesions might precede the skin eruption, as in a case observed by Sir Malcolm Morris, in which such lesions occurred two years before the skin was affected. The disease occurred in the vulva in the form of milk-white patches on the inside of the labia. Wandering or geographical rash on the tongue was a harmless disease and had never been seen by the speaker in association with any disease of the skin. As regards psoriasis, Sir Malcolm Morris could not confirm Fordyce's experience that it might affect mucous membranes. In tinea circinata and in a few cases of sclerodermia the disease had been known to spread to mucous surfaces. Rhinoscleroma might also spread to the mucous membrane of the nose. Acanthosis was another rare disease in which the mucous membranes of the mouth and vagina might be attacked. Sir Malcolm Morris briefly referred to the treatment of affections of mucous membranes; it should be directed to the disease of which the mucous membrane lesions formed a part. Strong caustics should be avoided and a weak chromic acid solution (5 per cent.) was often beneficial.

The subject was discussed by Dr. LOUIS WICKHAM (Paris), Professor R. B. WILD (Manchester), Dr. J. GOODWIN TOMKINSON (Glasgow), Dr. J. H. SEQUEIRA (London), Dr. H. H. B CUNNINGHAM (Belfast), Dr. S. E. DORE (London), and the PRESIDENT.

Sir MALCOLM MORRIS replied.

Dr. J. GOODWIN TOMKINSON read a paper on

The Ætiology and Treatment of Pruritus Ani,

which was discussed by Dr. F. HOWARD HUMPHRIS (London), Dr. J. METCALFE (Bradford), and Dr. A. W. LOXTON (Birmingham).

Professor R B. WILD read a paper, illustrated by photographs and microscopical sections, on a case of

Acanthosis Nigricans.

Mr. G. L. ST. GEORGE (Lisburn) and Dr. G. MONCRIEFF MELVILLE (Youghal) read a paper on another case of the same disease, with photographs and sections, the patient having been shown earlier in the meeting.

FRIDAY, JULY 30TH.

The proceedings were opened with a discussion on

The Supposed Risks attending the X Ray Treatment of Ringworm.

Mr. R. HIGHAM COOPER (London), introducing the question, divided his subject into two parts: (1) injuries to the scalp; and (2) injuries to the brain. He said that injuries to the scalp could not be called "supposed" risks, as most workers had, unfortunately, come across one or more instances, but these were now happily rare since Sabouraud introduced his admirable technique. He (the speaker) had met with four distinct varieties of scalp injuries: (1) Visible [illegible] and (4) permanent alopecia unaccompanied by visible dermatitis. The second and third were the varieties commonly found and were due to overdosage. The first was due to the use of too soft and the fourth to that of too hard a tube. It was very necessary to keep the vacuum of the tube within certain limits, and he suggested the following methods. A tube was used which was fitted with a mica disc regulator. The wire attached to this was pushed down until the end of it was three inches from the cathodal terminal. Suppose the tube to be very hard, some of the current would pass round through the auxiliary tube, and, although it might not lower the vacuum, yet none of the injurious penetrating rays were produced and treatment might be continued, the only disadvantage being the increased time it would take on account of the waste of current. The operator must guard against the vacuum becoming too low by stopping treatment, not when the tube became blue, but when it showed signs of reversals. Another method was to fix a piece of metal on an ampèremeter in the primary circuit in such a position that the needle when it indicated a certain ampèrage completed an electric bell-circuit (or, by inserting a relay, cut out the current to the primary of the coil). The use of this depended upon the fact that more current passed through the tube when it became soft, and *vice versâ*. A hot-wire ampèremeter must be used, as the oscillations in other types would spoil the experiment. Turning to supposed risk of injury to the brain, Mr. Cooper said that out of all the tens of thousands of cases treated during the past six or seven years not a solitary case of injury had been reported. He had carried out experiments on the lines of those recorded by Dr. J. M. H. Macleod in THE LANCET of May 15th last, and was pleased when he saw Dr. Macleod's paper to note that their results were identical. He would not describe his experiments on the effects of a single dose upon the cortex immediately beneath, beyond saying that the dose was about one-twentieth of a pastille. He had imagined that there was some part of the brain which (during a total epilation) would receive some rays from each exposure and be more affected than the brain *immediately* beneath the cranium in a single exposure. He had experimented with a cranium by a method which he described. He concluded that there was a spot at which a number of rays converged, but that at that spot the actual dose received was about one seventy-fifth of a pastille. The whole question of risk depended upon the least dose of X rays which could possibly cause harm. He had always regarded anything less than one pastille dose as *stimulant*, one pastille dose or a little more as *temporarily inhibitive*, and a greater dose than that as destructive. He concluded that in cases of ringworm, if the brain received a dose which could produce any effect at all, it could only be evanescent and of a stimulating nature. He concluded that there was no risk of injury to the brain, and, where Sabouraud's instructions were faithfully followed, very little risk of injury to the scalp, and further, that even this risk would disappear with improved apparatus, especially as regards regulation of the vacuum of the tube.

Dr. Margaret Dobson (Bradford) said that she had had three cases of dermatitis of the scalp; in all of them the megalosporon endothrix was present. She suggested that cases of ringworm in which this spore was found might be more prone to X ray dermatitis than others.

Professor Wild had found that private patients objected to the temporary alopecia caused by the X rays. He considered the treatment justifiable where a quick cure was urgent. He thought there was no proof that X rays killed the spores, and therefore parasiticidal remedies should be used after epilation to complete the cure. He had noticed several times that the hair when it grew again was coarser in texture and lacking in brightness, this being apparently due to partial atrophy. He agreed that there was no risk of injury to the brain.

Dr. J. H. Sequeira said that he had treated 1400 cases by the pastille method. He considered risk of injury to the brain was purely imaginary. At the same time he preferred not to treat children under three years of age, where the fontanelles were not properly closed. 267 of his cases had come from institutions where they were under expert examination of both medical officers and school teachers. From these he had had a report that in no single instance was there, after several years' interval, the slightest evidence of any delayed development or other injury to the brain. Sabouraud, Fox, Adamson, and Macleod were unanimous in the same statement. Dr. Sequeira had himself experimented on similar lines with confirmatory results. As to methods of treatment, he gave smaller doses where the hair was fine in texture, considering it more responsive than coarse hair. He thought that for purposes of measurement the tachymeter was useless. He regarded the X ray treatment of ringworm as rapid, efficient, and safe, but made it a rule that in every case the child's parent gave a written guarantee that no legal proceedings would be taken should dermatitis or alopecia result.

Dr. R. W. MacKenna (Liverpool) considered that the evidence given was sufficient for a verdict for the X rays of "not guilty" of causing injury to the brain, and his own experience would accord with such a verdict. At the same time, he agreed with Dr. Sequeira that X rays should not be used for too young a child; personally he only treated children above five years of age. As to alopecia without dermatitis, such a condition often occurred in cases of ringworm where no X ray treatment had been given. With regard to Dr. Dobson's remarks on endothrix, he thought the condition due to lessened vitality in the surrounding cells. He thought it very important that the genuine pastilles should always be used.

Dr. R. E. Howell (Middlesbrough) asked if it were a common experience for the hair to turn grey. This had happened in the first case he treated some years ago.

Dr. S. E. Dore considered that there was no risk to the brain. In confirmation of this opinion he instanced cases of extensive rodent ulcer which had been subjected to large doses over an extended period without the slightest apparent effect on the brain. He mentioned that epilepsy had been treated with X rays, but did not know with what results. If X ray treatment produced any effect at all upon the brain he should think it would be that of temporary stimulation. He agreed with Mr. Cooper that the drowsy and other effects occasionally met with for a day or so after treatment were due to the somewhat alarming apparatus of the so-called "spark specialist." He asked Mr. Cooper what was the area in the brain to which most of the rays converged.

Dr. Sequeira then read a communication from Dr. A. Howard Pirie (London), in which he described a case treated four years ago. Permanent alopecia had resulted, but there was no evidence of any ill-effects on the brain. Dr. Pirie believed in very careful regulation of the current used to ensure uniform dosage.

The President thought that in consideration of the weight of evidence from all quarters they might regard the spectre of brain trouble abolished.

Mr. Cooper, in reply, said that he thought germicidal agents should always be used in hospital cases, not, however, with the object mentioned by Professor Wild, but to prevent re-infection. In his experience that was the greatest trouble which had to be faced, and a germicidal application, such as a mercurial ointment, was necessary in the case of children living under conditions of dirt and squalor. While not maintaining that the X rays directly killed the spores, he found the disease cured by the use of X rays alone, where either the whole scalp was epilated at once, or (as in the case of most private patients) ordinary precautions were taken to prevent re-infection. He did not agree that the new hair was normally atrophic in character or grey in colour. His experience showed it to be slightly darker and stronger, and usually more curly. Deficiency in lustre and pigmentation were due to overdosage, and that was the result aimed at in Noiré's treatment of hypertrichosis. Mr. Cooper mentioned a case of his own treated with a "super-pastille" dose through a filter, with the object of permanently removing the hair. He found that some hairs returned, but were dull, white, and brittle. Probably if he had slightly increased the dose none would have returned. Answering Dr. Dore, as far as he could make out the greatest number of rays converged to about the centre of the corpus callosum. He thought Dr. Sequeira's records of cases from institutions exceedingly valuable, as there was usually such difficulty in keeping in touch with patients years after treatment, though one usually heard if the case went wrong. In conclusion, he thought that after that morning's discussion they might quite relieve their minds of fears as to possible injury to the brain.

Dr. S. W. Allworthy (Belfast) described a case of

Cutaneous Actinomycosis,

showing photographs before and after treatment. The disease apparently originated from chewing raw oatmeal. A tumour was removed and potassium iodide and X rays (30 exposures) were given with good results.

Professor Wild mentioned three cases. He believed in pushing the iodide very far as it was so quickly excreted, 80 per cent. being eliminated in three hours.

The President also described several cases.

Dr. F. Howard Humphris (London) read a paper on

Some Practical Uses of Static Electricity.

He advocated the use of static currents for the relief of pain, particularly in overcoming areas of congestion; instancing sciatica, he said that the pain was relieved by inducing rhythmical tissue contraction or "cellular protoplasmic massage" under which stasis cannot exist. A single administration was gratifying, but treatment should be continued once or twice daily for a week and then gradually discontinued. Where sparking was not well-borne the brush should be given.

Dr. Munro (New York) agreed as to the value of static currents in the relief of stasis; their use was particularly indicated in acute lumbago and prostatitis.

Dr. J. Metcalfe (Bradford) considered high-frequency currents generally more beneficial, but not in nerve cases. He instanced a very bad case of costal neuritis which had been cured by static electricity. He had found these currents useful in Bell's and post-diphtheritic paralyses.

In reply, Dr. Humphris thought that failures in the use of static currents were generally due to lack of knowledge or of a sufficiently powerful machine.

Dr. E. B. Hazleton (Sheffield) in a short paper on

X Rays in Gynæcology,

advocated their use where it was advisable to render a woman sterile and for the reduction of fibroids and of offensive discharges.

Mr. Cooper, while agreeing that men and small female animals were sterilised by exposure to X rays, thought that the ovaries in an adult woman were too well protected for X rays to cause permanent sterility without seriously affecting the superficial structures.

Dr. Sequeira then read a paper on

Idiosyncrasy and X ray Treatment,

communicated by Mr. J. Hall-Edwards (Birmingham) who was unfortunately too unwell to be present. In the author's opinion old cases of "burning," which were put down to idiosyncrasy, were really the result of faulty exposure. He quoted the opinions of most X ray workers who were, almost without exception, of the opinion that idiosyncrasy did not exist. Personally he thought it did exist, but to a very slight extent, and not enough to be dangerous. He mentioned that in many cases pigmentation was due to an idiosyncrasy and not necessarily in proportion to the dose of X rays.

Dr. Humphris thought that many of these so-called cases of idiosyncrasy were due to varying amounts of reverse current passing through the tube, and suggested that they might not occur if the tube was excited by a static machine, the current from which was unidirectional.

Mr. COOPER said that all Sabouraud's work was done with static machines. Pigmentation was frequently due to a drug which the patient was taking, and he mentioned cases of deep pigmentation when the patient was given arsenic (as in leukæmia).

Dr. SEQUEIRA confirmed Mr. Cooper's observation on arsenic and described the case of a student at the London Hospital who received a dose of X rays and subsequently took some arsenic, with the result that several days later deeply pigmented spots appeared.

The work of the section closed with a vote of thanks to the President.

HÆMATOLOGY AND VACCINE THERAPY.

THURSDAY, JULY 29TH.

President, Sir ALMROTH WRIGHT (London).

Professor CALMETTE (Lille) opened a discussion upon the

Early Diagnosis of Tuberculosis for the Effective Treatment of that Disease.

He stated that his own researches in conjunction with those of Bartel, Orth, and Rabinovitch had established (1) that tuberculosis remains localised for a longer or shorter period in the lymphatic glands in connexion with the organ first infected; (2) that the rapidity and intensity of the infection depend on the virulence of the infecting organism; (3) that when the bacilli are neither numerous nor virulent then they may be destroyed in these glands, or the infection may be arrested by calcification of the glands; and (4) that serious tuberculous lesions result either from a single infection in bulk or from numerous infections frequently repeated at short intervals. This last reason would account for the spread of the disease in cattle in infected sheds and in men in infected houses. Professor Calmette laid stress on the importance of diagnosing the infection before it had advanced far enough to give definite physical signs. He condemned the subcutaneous injection of tuberculin for the following reasons: (1) there is a general febrile reaction accompanied by local congestion with possibly a dangerous diffusion of bacilli; (2) it is not practicable in febrile patients; and (3) cases of aggravation of the disease might, rightly or wrongly, be attributed to the injection of tuberculin. The local reactions were preferable, and of these the cuti-reaction of von Pirquet had the disadvantage that it gave positive results in healed cases as well as those in which the disease was active, so that 55 per cent. of all adults gave positive results. In children under three years of age, however, only 4 per cent. of apparently healthy children gave the reaction, so that in children under this age it was of value in diagnosis. The ophthalmo-reaction had the advantage of only showing tuberculous lesions actually in evolution. It also showed to some extent the degree of the infection, the reactions in the more recent cases being clearer and more intense. He had found that those cases which showed the greatest reaction had also showed the presence of the largest quantity of antibodies when tested *in vitro* with tuberculin by the Bordet-Gengou reaction. In some extensive and [illegible] was either delayed [illegible] of apparently he[illegible]e of the tuberculous patients 92 per cent. reacted, these figures being taken from an analysis of 20,000 cases. He did not think that the test was of any value in prognosis, for he found that the amount of antibodies to the tuberculin was in no way relative to the gravity of the disease. The test was not dangerous, but precautions must be taken to see that the eye was healthy and that the tuberculin was aseptic and pure. With these precautions he had only had 80 cases out of his 20,000 (or 0·4 per cent.) in which the reaction had been very severe, so that there was less danger in the procedure than in the exposure to X rays or the puncture of a vein. He maintained that there was no hypersusceptibility in [illegible] test were repeated af[illegible] were obtained it was [illegible] Professor Calmette s[illegible]gnosis of tuberculosis thus: 1. By reactions called "reviviscent," which consist in making a conjunctival or other local reaction appear in patients who are carriers of tuberculous lesions or by the injection of tuberculin subcutaneously. 2. By study of the humoral or phagocytic reactions—(*a*) activation of cobra venom by serum or milk of tuberculous subjects; (*b*) deviation of the complement with tuberculin or extract of tubercle bacilli; and (*c*) opsonic index by Wright's method. He considered that by applying these methods periodically in communities such as schools it would be possible to isolate the carriers of bacilli, by which means the chief cause of the aggravation of the disease would be prevented and the patients could then be put in the way of a cure and possibly of an antituberculous immunity.

Professor W. ST. CLAIR SYMMERS (Belfast) said that one of the great features about such meetings was that it enabled them to come in contact with those men with whose writings and works they were familiar. The ophthalmo-reaction for which they were indebted to Professor Calmette had, he thought, fallen rather into disuse in this country owing to certain dangers which had been met with. However, he had no doubt that when the practitioners appreciated the results which had been put before them it would be restored to favour.

Professor E. J. MCWEENEY (Dublin) said that he had tested some cases both by Calmette's and von Pirquet's methods and his results agreed with those of Professor Calmette.

Dr. THOMAS HOUSTON (Belfast) said that he had found the ophthalmo-reaction too sensitive and there was a possibility of making a diagnosis of tubercle on it when really the lesion was of a different nature although the patient might have some slight tuberculous infection. He preferred to use the opsonic method of diagnosis. He mentioned several cases in which there was a definite ophthalmo-reaction, but which the subsequent history showed to have been cases of typhoid fever, although possibly a latent tuberculous focus was present.

Dr. W. H. WILLCOX (London) said that he had found the ophthalmo-reaction very reliable, but in several cases there had been severe conjunctivitis. He preferred the opsonic test, especially when a series of three or four indices were done before and after some massage or exercise.

Dr. A. C. INMAN (London) said that he had tested the opsonic indices of a number of patients who had had Calmette's test done and had found that it acted as an inoculation of tuberculin, and in some cases a considerable negative phase was induced.

Professor WILLIAM OSLER (Oxford) emphasised the fact that a considerable number of the people present in the room would give positive reactions by Calmette's test, although they were in no sense dangerous to the community. He distinguished between open and closed cases of tubercle, the former being a source of infection, but the latter being quite safe, and therefore not to be cut off from free intercourse with the community.

Dr. INMAN next read a paper on

The Value of the Opsonic Index in the Diagnosis and in the Regulation of Treatment of Tuberculosis.

He maintained that the study of the opsonic index, and more especially the study of the phenomena of auto-inoculation, had given them a very much clearer conception of such a complicated disease as pulmonary tuberculosis. Owing to the limited time at his disposal he touched on only four ways in which the opsonic index was of assistance in the study of the disease. I The early diagnosis of tuberculosis. The best method of applying the index for diagnosis was to examine the blood of the patient before and after some disturbance of the focus, by walking or breathing exercises in the case of pulmonary affections, or by massage or the application of a Bier's bandage in the case of localised approachable foci of disease. If fever were present and the patient confined to bed the blood should be examined in relation to the swing of the temperature and an inverse relationship of opsonic curve to temperature would suggest a tuberculous infection. The great advantage of this method of diagnosis over the old tuberculin test, the ophthalmo-reaction, or the cutaneous reaction, was that no tuberculin was introduced into the body. Latent or arrested tuberculosis frequently gave a positive ophthalmo- or cutaneous reaction, whilst the opsonic index only varied if "auto-tuberculin" coming from the diseased focus was affecting the blood. Under the latter circumstance evidence was afforded that the patient required immediate treatment. II. By blood examinations Dr. Inman had been able to distinguish between the following groups of tuberculosis. 1. Cases in which the blood was varying from hour to hour, the patient being kept at rest (spontaneous auto-inoculations occurring). These cases were febrile. 2. Cases in which the opsonic index did not vary so long as the patient was kept at rest, but varied as the result of exercise (auto-inoculations inducible by exercise). Such auto-inoculations might be excessive and were then dangerous, but if not excessive they were harmless or even advantageous. 3. Cases in which the opsonic index did not vary even after the hardest labour. The disease was here probably arrested. III. The opsonic index indicated the rational treatment of tuberculosis so far as they could go to-day. 1. It had shown the importance of absolute rest in the active stages of the disease. 2. It had explained the effect of graduated labour employed as a therapeutic agent in the treatment of phthisis and the action of Bier's passive congestion method for surgical tuberculosis. 3. It had given a satisfactory means of controlling tuberculin inoculations, as well as of selecting suitable cases for the treatment. IV. The opsonic index afforded a valuable guide as to whether the disease was arrested or not. If restoration to previous good health were accompanied by a normal index before and after active or passive movement of the focus of infection, this might be taken as evidence of the arrest of the disease.

Dr. A. BUTLER HARRIS (London) said he was glad that the time had arrived when the profession recognised that the opsonic index was no mere phantasy of Sir Almroth Wright. He himself had found the index of great use both in the diagnosis and in the treatment of tuberculosis. He did not think, however, that although after treatment a patient showed a persistently normal index for a considerable time he was necessarily cured, and related a case to bear out this point.

Mr. S. MAYNARD SMITH (London) read a paper on

The Inoculation Treatment of Tuberculous Arthritis.

He described the results of an investigation which he had carried out from the point of view of a surgeon into cases that had been treated in the inoculation department of St. Mary's Hospital, London, during the past few years. These cases were 72 in number, and of these 34 attended for examination in response to communications. (Printed particulars of these cases were handed to the meeting.) It was shown that, of the 34 cases, only five were treated by inoculation from the time that they first came under observation. Four made such complete recoveries that it could not be determined which had been the diseased limb; the fifth was cured, some deformity and limitation of movement remaining. In 12 cases splinting, rest, or operation, had been carried out for 12 months or less before inoculation. In 11 of these a cure ensued, in seven with complete restoration of function; the twelfth case had improved and was still under treatment. Of the remaining cases two had had only two months' treatment; in two more no improvement had taken place after six and ten months' treatment respectively; nine were cured, with more or less complete restoration of function; and four had improved and remained under treatment. To turn to another point of view, eight had had sinuses, and in every one of these the sinus had healed except in the case of a man who ceased to attend after six months. In one case the sinuses broke down again after two years, but were now rapidly closing again with recommencement of tuberculin treatment. The question of the use of the opsonic index in diagnosis and in deciding when cure was complete was also dealt with, and, lastly, the ways in which surgical treatment should be combined with vaccine therapy.

Dr. D. W. CARMALT-JONES (London) continued the discussion with a paper on

A Review of the Inoculation Treatment of Tuberculosis.

The paper was a critical review of the cases of tuberculosis treated in the department of therapeutic inoculation at St. Mary's Hospital during the last five years under Sir Almroth Wright. The sites of infection, such as glands or skin, were considered separately, and note was taken of circumstances, such as dose, age, or secondary infections, which might influence results. The object was to enable the prospects of success in any given case to be estimated—that is, it was an attempt to establish prognosis. The patients all attended as out-patients, the records had the usual out-patient imperfections, and it should be noted that the patients had had no advantages except inoculation. The numbers of each kind of case treated were as follows: lymphatic glands, 87; ulcer, sinus, and abscess, 50; genito-urinary tract, 34; lupus, 23; lungs and pleura, 10; bone, 8; dactylitis, 7; peritonitis, 5; eye, 3; and larynx, 2. Tuberculous lymphatic glands, the most numerous class, were studied in greater detail. In all the cases the patients had been personally interviewed. The estimates of results in other sites were made from the records only. Lymphatic glands, 87 cases:—In eight inoculation was only an adjunct to removal by operation; no recurrences were recorded. In 79 cases inoculation was the chief method employed; the patients were inoculated subcutaneously with tuberculin (bacillary emulsion) at intervals of ten days; the doses were minimal at the outset, and were not increased till they ceased to have a therapeutic effect. Free fluid was drawn off by a syringe, and sources of irritation, such as carious teeth, received local treatment. Secondary infections were treated with appropriate vaccines. When glands had disappeared altogether, or had been reduced to the size of cherry-stones, they were considered "cured"; when they remained as large as raisins they were called "much better"; when slightly reduced they were called "better," and others were described as "unchanged" or "worse." 27 cases were cured, 22 much better, 18 better, 8 unchanged, and 4 worse. Age was the most important factor in prognosis; the greatest proportion of good results occurred in young children and in young adults from 15 to 25 years of age; the lowest proportion of good results and the highest of bad occurred at about the age of puberty. The minimal dose was 1/20,000th milligramme for children and 1/15,000th for adults, and the maximal was 1/10,000th and 1/4,000th milligramme respectively. Relapse, after attaining to some degree of improvement, had occurred in 11 cases. Ulcer, &c., 50 cases:—10 cured, 20 much better, 9 better, 8 unchanged, 3 unknown. The dose was 1/15,000th to 1/7,000th milligramme for children and 1/15,000th to 1/5,000th milligramme for adults. As before, the best results were obtained in young children and young adults, and the worst in children from 10 to 15 years of age. Secondary infections occurred in more than half the cases. Treatment lasted on the average about a year. Relapse occurred six times. Genito-urinary tract, 34 cases (testis 9, kidney 8, bladder 17):—7 cured, 8 much better, 13 better, 3 no better or worse, 3 unknown; 5 relapses occurred. The dose was 1/25,000th to 1/4,000th milligramme, a small initial dose being important. Treatment generally lasted a year. Secondary infections occurred in half the cases. Lupus, 23 cases:—3 cured, 8 much better, 9 better, 1 unchanged, 2 unknown; there were 5 relapses. Dose, 1/10,000th to 1/2,000th milligramme. Treatment had lasted two years. Secondary infections were common. Phthisis, 10 cases:—4 much better. The following were also much better: bone 5, dactylitis 2, peritonitis 1, and eye 3. General prognosis:—Glands 1 in 3 cured, 5 in 8 much improved. Ulcer 1 in 5 cured, 3 in 5 much improved. Genito-urinary tract, 1 in 5 cured, 3 in 7 much better. Lupus, 1 in 8 cured, 1 in 2 much better. It was submitted that such results obtained among out-patients proved the very high value of inoculation in the treatment of tuberculosis.

Dr. MARCUS S. PATERSON (Frimley) read a paper on

Auto-inoculation in Pulmonary Tuberculosis.

He explained that he used the word "auto-inoculation" to mean the effect of exercise on the blood as shown by the clinical signs. At first when he had prescribed graduated labour for his patients at the Brompton Sanatorium, he did it rather with the view of avoiding the lazy habits so frequently acquired at sanatoriums, but he soon noticed that many patients who did not improve on lighter work obtained marked benefit when put on more laborious tasks. This led him, in conjunction with Dr. Inman, to regard the whole process as one of auto-inoculation, which supposition was borne out by the serum tests carried out by Dr. Inman. This theory, Dr. Paterson said, had brought him from working in the dark to working with open eyes and had fixed a point at which to aim to find out how much useful work a patient could do without rise of temperature and with decrease of sputum. It had also enabled him materially to shorten the stay of the patient in the sanatorium, so that he was now able to treat 50 per cent. more patients at Frimley without the addition of a single bed. Dr. Paterson laid especial emphasis on the means at disposal for controlling excessive auto-inoculation. Such a condition was constantly occurring in febrile patients, so that in such cases the first thing to do was to keep the patients at *absolute* rest. At first, before he and wash themselves, but more recently he had found that even this should not be allowed and the rest should be absolute. Cough should be carefully controlled, as a patient who coughed violently shook the whole bed and was, as regards foot pounds of work, taking fairly vigorous exercise. The indication of excessive auto-inoculation in the graduated labour patients was a temperature of 99° F., *plus a headache*, and such cases were treated with absolute rest and after about a week they were, as a rule, able to return to work. Dr. Paterson showed charts illustrating the effect on the temperature of excessive auto-inoculations and of the various grades of labour from absolute rest to navvy work. He summarised modern sanatorium treatment as follows:—1. Placing patients under ideal hygienic conditions and keeping them at rest. 2. The same *plus* tuberculin inoculations 3. Prevention of excessive auto-inoculation. 4. Inducing auto-inoculation by graduated exercise or work.

FRIDAY, JULY 30TH.

Professor **BORDET** (Brussels) opened a discussion on

The Infections of the Respiratory Tract

with a paper on the Micro-organism of Whooping-cough. He stated that the researches undertaken with Dr. Gengou in 1906 had caused him to [illegible] cough a small cocco-bacillu [illegible] and staining feebly with [illegible] This, he said, is found ir [illegible] in pure culture, in the exudate, [illegible] rom the depths of the bronchi, [illegible] in the characteristic paroxsyms of cough. The first cultures are difficult to obtain because the organism after leaving the body develops rather slowly, the colonies not being readily seen till the third day [illegible] for their cultivation. [illegible] been mixed a large pr [illegible] Isolation is by no m [illegible] besides the specific organism, only a very few contaminating microbes, the commonest of which are the pneumococcus, streptococcus, or the influenza bacillus. The organism of whooping-cough bears a certain morphological analogy to the influenza bacillus, but it is readily distinguished by its cultural characteristics and by the reaction of immune sera. Professor Bordet's organism grows readily in liquid media containing blood or serum if such medium is spread in a thin layer freely exposed to the air. If the cultures are filtered the filtrate does not appear to possess any very evident toxic properties. But by taking the bodies of organisms grown on solid media a poison can be prepared, by employing the method devised by Besredka for obtaining endotoxins, which is very active and produces the essential symptoms of whooping-cough. The poison has a marked power of necrosis. Injected in minimal doses into the subcutan [illegible] necrosis of th [illegible] large areas, [illegible] fatal; the results are the more remarkable since the toxic extracts employed contain only very small amounts of bacterial substance. Further, this suggests that in whooping-cough the long duration of the period of cough is due to necrosis of the cellular lining of the bronchi, and this is supported by the findings of some histologists. The serum of patients who have recovered from the disease shows specific reactions to the organism. Thus, the fixation of the complement which was devised by Bordet and Gengou in 1901, and which has since been applied to many diseases, notably syphilis, is readily demonstrable. This, in addition to the bacteriological findings, furnishes very strong proof that the organism is the real pathogenic agent in whooping-cough.

Dr. J. **FREEMAN** (London) continued the discussion by narrating his experiences with Professor Bordet's whooping-cough organism. He emphasised the difficulty in recognising and isolating the bacillus in the sputum by reason of its slow growth and its resemblance to the influenza bacillus He was convinced that the organism was the etiological factor in whooping-cough as the serum of patients suffering from this disease agglutinates the bacillus sometimes in as much as a 64-fold dilution. The complement deviation method of Bordet-Gengou also gave confirmatory evidence. The fact also that Dr. Bordet had inoculated some children with a vaccine of the organism and had produced a very severe estimations, [illegible] the organism he had met with no success in this direction. He had performed over 10[illegible] ing from whooping-cough, [illegible] of vaccine of the bacill [illegible] Owing to the lack [illegible] he had found it very difficult to [illegible] ly, but with doses varying from [illegible] he had found that there was a distinct advantage in the cases inoculated with vaccine over those inoculated with salt solution, the difference being most marked where the large doses were used. He thought that when the question of dosage had been worked out properly the vaccine would prove very valuable in the treatment of whooping-cough.

Dr. W. H. **WILLCOX** (London) and Dr. W. **PARRY MORGAN** (London) communicated a paper on

The Treatment of Pneumonia by Inoculation.

The paper was based on the treatment by inoculation of 24 cases of acute pneumonia, most of these cases being patients of St. Mary's Hospital, London, under the care of Dr. Willcox. It was emphasised that vaccine treatment was a valuable therapeutic measure, but that it was not intended that it should replace other forms of treatment which should include the usual approved therapeutic measures. The authors did not consider it wise to give any statistics as to the mortality rate of cases treated by vaccine because, although their results had been extremely good, the number of cases was too small for any definite conclusions to be drawn. Three methods of procedure. in the preparation of an autogenous vaccine were described, cultures being made (1) from sputum; (2) from blood; and (3) by aspiration of the pleural cavity or superficial part of the consolidated lung by a small syringe with a fine needle. The choice of the particular method was discussed. As regards treatment it had been found advisable to commence by the administration of 20,000,000 to 50,000,000 of stock pneumococci immediately the patient came under treatment. At the same time steps were taken to prepare an autogenous vaccine. After 24 to 48 hours a second dose might be given, and further doses if necessary. It was considered important that as the crisis neared the dose should be decreased, since the patient became more susceptible to inoculation at this period. The details of the 24 cases investigated and the clinical effects produced in them by vaccine were described. It was found in many instances that there was an immediate fall of temperature, and the dyspnœa and delirium became less. The duration of the disease appeared in some cases to have been shortened, the crisis occurring in six cases before the usual time. Sometimes the fall of temperature was by lysis instead of by crisis; this happened in eight of the cases, a larger proportion than would have been likely without vaccine treatment The most convincing evidence of the benefit derived from vaccine was shown by those cases which ran a protracted course. In these cases after inoculation almost immediately the temperature fell and the symptoms rapidly cleared up. This improvement could have been due to no other cause than the vaccine, since before this was given all the usual methods of treatment had been adopted without avail. In some cases an autogenous vaccine was found to give decidedly better results than a stock pneumococcus vaccine. The authors emphasised the importance of commencing vaccine treatment as early as possible in the course of the disease.

Dr. A. **BUTLER HARRIS** (London) said that he had been using vaccines for pneumonia for the last two years with very beneficial results He had seen a crisis on the first day of the disease 11 hours after inoculation He thought a stock vaccine made from a virulent strain of pneumococcus was quite efficient

Dr. **MORGAN**, in reply, said that he had found differences in the serum reactions of pneumococci of various origins and had even seen one obtained by lung puncture agglutinated by the patient's serum, although a strain isolated from the throat of the same patient was not so agglutinated. In his experience stock vaccines failed entirely in some cases.

Dr. C. H. **BENHAM** (Hove) read a paper on

The Bacteriology and Vaccine Therapy of the Common Cold.

He suggested that during seasonal epidemics of catarrh a considerable number of the ordinary saprophytes of the upper air passages probably became pathogenic. The organisms he had found in the nose were: (1) micrococcus catarrhalis; (2) micrococcus paratetragenus; (3) bacillus septus; and (4) bacillus of Friedlander, and more rarely the pneumococcus and influenza bacillus. He thought the first four were the usual infective agents of the common cold. The micrococcus catarrhalis caused both acute and chronic colds with very irritable cough, some coryza, and pyrexia. The micrococcus paratetragenus (Bezancon and de Jong) was often associated with it and caused similar symptoms. The bacillus septus (Cautley) was seldom a cause of coryza, but it produced mild pharyngitis, with painful throat, nervous depression, and muscular pains. It was a diphtheroid bacillus with cultural reactions differing somewhat from bacillus diphtheriæ and bacillus Hoffmanni. Charts were shown of three cases of acute cold, one of "influenza," and one of chronic cold. In all of these the administration of micrococcus catarrhalis vaccine was followed by a rise in the opsonic index and a marked improvement in the clinical symptoms. Dr. Benham concluded from his work that vaccine therapy was the most efficient way of treating such diseases.

Dr. FREEMAN thought that the pneumococcus and streptococcus ought to be assigned a more important rôle in the production of such diseases, as he had found them of very frequent occurrence.

Dr. BUTLER HARRIS said he had found that the micrococcus catarrhalis, the pneumococcus, and the bacillus septus were the most frequent inhabitants of the nose. He did not think the clinical condition was any indication of the bacteriology. He instanced several cases of acute "sore throat" which were caused by micrococcus catarrhalis and which cleared up within 12 hours of the administration of one dose of vaccine.

The PRESIDENT offered himself as an example of the influence of vaccines on chronic infections of the respiratory tract. Although he had suffered from chronic bronchitis for 30 years, after a few doses of his own pneumococcus the condition entirely cleared. He laid stress on the importance of the influenza bacillus in many of these conditions.

Dr. D. W. CARMALT-JONES (London) followed with a paper on

The Treatment of Bronchial Asthma by a Vaccine.

He suggested that the spasmodic dyspnœa which was such a distressing symptom in many cases of chronic bronchitis was due to a specific bacterial toxin, the result of a definite infection, and was amenable to treatment by a corresponding vaccine. He isolated from a case of bronchitis with spasmodic dyspnœa a short Gram-negative bacillus with rounded ends, non-motile, growing readily on ordinary media, and not fermenting any of the common sugars. The patient after three doses of from 20,000,000 to 30,000,000 of a vaccine prepared from this bacillus lost all her dyspnœa. There was a slight recurrence three months later which disappeared with a renewed administration of vaccine. The speaker had used the same vaccine in over 50 similar cases since, but the results were difficult to gauge, as the degrees of disability at the outset were very variable. The condition was markedly intermittent and the symptoms were largely subjective, so that results depended on the patients' statements. In some cases the results of treatment were remarkable, and out of 52 cases treated 13 lost all their symptoms, only four completely failed, the remainder receiving varying degrees of benefit either in the frequency or severity of the attacks. Attempts at serum diagnosis had failed, but the fact that the vaccine had been so effective was, in Dr. Carmalt-Jones's opinion, strong presumptive evidence that the dyspnœic attacks were due to a specific organism.

The proceedings of the section were closed with a paper by Dr. ALEXANDER FLEMING (London) on

The Bacteriology and Vaccine Therapy of Acne Vulgaris.

The author emphasised the importance of the acne bacillus in the etiology of this condition, a subject which he had elsewhere discussed at some length.[1] The medium which he had found best for the growth of the bacillus was ordinary nutrient agar to which had been added 1 to 5 per cent. of oleic acid, but even on this it was necessary to plant out the pus very thickly to obtain a growth. In the treatment of acne he had obtained exceedingly good results with a vaccine of the bacillus, either alone or in combination with staphylococcus vaccine in those cases where there was a mixed infection.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

WEDNESDAY, JULY 28TH.

President, Dr. STCLAIR THOMSON (London).

The PRESIDENT expressed his pleasure at the honour which the Council had conferred upon him by electing him as President. He regretted the untimely death of Dr. Robert Allen, who had so well aided him in drawing up their programme, which had been carefully considered, and had been arranged with special reference to questions affecting the profession generally. In tinnitus they had a trouble that was widespread, and in the discussion upon diphtheria they would have the advantage of an expert clinician, a skilled bacteriologist, and an able guide in state medicine; while in the treatment of laryngeal stenosis they were to have the pleasure of hearing a prominent British surgeon, together with an eminent American authority; and they would also hear the views of a laryngological expert from Brussels. After a few remarks upon the pronunciation of the word tinnitus the President introduced

Dr. THOMAS BARR (Glasgow), who then read a paper on

The Treatment of Tinnitus Aurium from a Non-operative Standpoint.

Dr. Barr referred to the difficulty in finding its cause, which might be in the conducting or receptive apparatus, and which might be simple as in cerumen, or complicated as when due to oto-sclerosis, to intralabyrinthine or to intracranial involvement, or to some general affection, as kidney or heart disease, diabetes or gout, in all of which treatment appropriate to the case should be given; for example, neurasthenia might be either cause or effect, but in either case prolonged rest, tonics, and change of air were indicated. He believed that oto-sclerosis, which was often associated with anæmia, required general rather than local treatment. Digitalis was useful in the pulsating form, whereas alcohol generally aggravated it. Bromides, hypnotics, and sedatives were referred to and the indications for their use mentioned. The action of fibrolysin in the absorption of fibrous adhesions was touched upon. The sometimes doubtful results of quinine and salicylates were pointed out, and the indications for, and objections to, their use discussed. Bromides were probably useful at bedtime and sometimes gave great relief. Paraldehyde also was at times beneficial. Potassium iodide was useful in the forms associated with vertigo even with no evidences of a specific diathesis. He thought that pilocarpine was indicated in those cases showing Ménière's symptoms. With reference to climatic conditions, he thought that bracing inland and upland air was good, without, however, over-exercise of the body. He considered that external applications of stimulating remedies, such as cantharides or liniment of mustard, to the mastoid process occasionally mitigated the noises. He dealt with massage of the tympanum with a vibratory frequency of from a few hundred to 2000 a minute, which he had found sometimes of benefit; but he laid stress particularly upon the good results obtained by the application of a tuning-fork to the affected ear, the pitch of the note of the fork being of an opposite character to that of the subjective noise (*tonbehandlung*). Electrical treatment he thought of little value and might be actually injurious. It was important to establish natural breathing and to see that the nasopharyngeal space was healthy. It should be remembered that tinnitus was occasionally due to dental decay.

Mr. R. LAKE (London), who followed, divided treatment into operative procedures remote from the ear and auditory apparatus and those dealing with any part of the auditory tract. Amongst the former were intranasal operations, lumbar puncture, and ligature of the carotid. The useful intranasal procedures for reflex tinnitus were removal of the posterior ends of the inferior turbinates and of spurs of the septum, which extended to the outer nasal wall. These conditions, though rare, required treatment if tinnitus were present with good hearing. Obstruction or irritation of the pharyngeal end of the Eustachian tube might require treatment. He gave Babinski's results of lumbar puncture, which showed 33 per cent. relieved, and thought these were rather due to an indirect effect upon blood pressure, as the endo- and peri-lymph spaces of the labyrinth were not in direct communication with the sub-arachnoid space; and he found that the tinnitus resulting from arterio-sclerosis was often modified or removed by remedies which lowered arterial tension. He referred to the early days when the tympanic membrane was trephined and other minor operations were performed which time and experience had modified or left behind. He considered that better measures were now adopted than division of the tensor tympani or even than section of the posterior fold. Of all these procedures he would prefer multi-section of the posterior fold. He did not think much of removal of one or more ossicles, but such might perhaps be tried before a major operation which destroyed the hearing altogether, if there were some hearing power to be preserved. He next dealt with the removal of the stapes, which operation was associated with the name of Jack. The results, however, were not quite what were hoped for. He reviewed methods of opening the labyrinth and of trephining the cochlea, which he thought better done with a radical mastoid operation to enable a better view to be obtained and which did not necessarily destroy the hearing' Ligature of the carotid he thought indefensible. He concluded his remarks with a description of what he considered the logical operation—i.e , ablation of the cochlea after a preliminary radical mastoid operation—giving descriptive cases. He strongly objected to division of the auditory nerve, which was very dangerous and had a high death-rate.

---

[1] THE LANCET, April 10th, 1909, p. 1035.

Dr. J. A. KNOWLES RENSHAW (Manchester) thought that tinnitus was far most frequently due to chronic middle-ear non-suppurative catarrh, or to the suppurative form, and in both cases he believed that this symptom became more and more severe. Its treatment had firstly to deal with all the accessory passages, as of the nose and Eustachian tube. It had been suggested that tinnitus was due to increased tension in the labyrinth caused by the indrawing of the foot-plate of the stapes, or to some obstruction of the lymph circulation by some contracting interstitial tissue, and he had therefore tried hypodermic injection of thiosiamine. He had used a 5 per cent. aqueous solution twice a week, increasing the dose from six to 35 minims. Latterly he had used an aqueous solution of 10 per cent. thiosiamine and 20 per cent. of glycerine in the same manner, and he had also tried fibrolysin. There had been a marked improvement in every case, but it was too soon to claim any permanency; still, he thought that it should be tried before operating upon the middle-ear or labyrinth for this trouble. In reply to a question by the PRESIDENT, Mr. RENSHAW stated that he had treated about 20 cases of chronic middle-ear disease, 12 of which were suppurating, and that all were relieved during the injections.

Dr. ANDREW WYLIE (London) considered that an attempt should be made to relieve tinnitus even though it could not be cured, and he had found that from one-twentieth to one-twelfth of a grain of calomel given every second night was of service. He had also tried passing hot air into the tympanum through the Eustachian catheter, and found it useful. The air was heated by an electric lamp and driven through the catheter by means of a foot pump—a contrivance of his own which he demonstrated.

Dr. G. W. HILL (London) considered that the surgical treatment had been fairly summed up by Mr. Lake. He himself had never opened the labyrinth for tinnitus because in two of his cases the cochlea had been exfoliated, and yet the tinnitus had remained. Of course, the tinnitus might be central, and then the absence of the cochlea would not improve matters, and division of the auditory nerve was useless as it really extended to the centre for auditory impressions.

Dr. J. [illegible] of the va [illegible] he did r [illegible] much to do with tinnitus beyond, perhaps, keeping up the tension of the membrane. He thought that syphilis was a frequent cause. He referred to the great nervous depression sometimes resulting and gave an instance in which it had led to self-destruction. With reference to treatment he used injections of chloroform and air alternately. He had removed the ossicles but had had no good results, but as surgical treatment had now so much advanced there was hope on these lines in the future He considered that there was great danger of facial paralysis in division of the auditory nerve.

Dr. R. H. WOODS (Dublin) laid great stress upon the fact that it was mere assumption to speak of a permanent increase of tension in the labyrinth caused by pressure inwards of the foot-plate of the stapes. This idea was based upon an experiment by Politzer, which he could not agree with. It could only occur for a short space of time because of the free communications of the labyrinth with the parts around.

Dr. A. LOGAN TURNER (Edinburgh) thought that it had not been proved that fibrolysin injected into the blood had any selective action upon fibrous tissue in the middle-ear, and that the good results mentioned by Dr. Renshaw might have been secondary to its action elsewhere in the body, as, for example, in cases of chronic gastric ulcer. Its introduction into the tympanum might possibly have a beneficial result.

Dr. BRYSON DELAVAN (New York) thought that the question was one of the greatest importance and congratulated the Association upon its choice of this subject for discussion.

A telegram of apology for non-attendance was here announced from Dr. H. Smurthwaite, a Vice-President.

The PRESIDENT stated that he had only recently written to Dr. Lermoyez's assistant about the hot-air treatment for nasal catarrh, and that he had received a reply that it was not thought so much of as formerly, and that it was considered that the results of its use were due rather to suggestion.

Dr. BARR replied, and thought that operation on the labyrinth generally gave more relief to the vertigo than to the tinnitus. It was interesting to hear Dr. Turner's suggestion *re* the indirect action of fibrolysin.

Mr. LAKE, in his reply, emphasised the importance of Dr. Woods's objection to the assumption of any permanent increase in intra-labyrinth pressure. With reference to ablation of the cochlea, the modiolus must be removed, for the bony cochlea might, as in Dr. Hill's case, be exfoliated and yet leave some nervous elements behind.

Dr. HUGH E. JONES (Liverpool) read a paper on

Preliminary Observations on the Association of Slight Abnormalities of the Auricle with Certain Forms of Deafness,

in which he referred to the smallness or absence of the lobule and other slight defects which had been considered to be associated with certain vicious or criminal tendencies. He thought that these defects were generally associated with disease which was not the result of acute inflammation, but rather was the result of imperfect development of the palate, the naso-pharynx, the Eustachian tube, or the tympanum, and he considered the defects could be explained upon these lines, where other more evident causes could be excluded. If so, this was important from the point of view of treatment and prognosis; for example, such patients had erroneously been considered as suffering from adenoids and operated upon for this condition, without, of course, any beneficial result.

The paper was discussed by Mr. G. JACKSON, Dr. DAN MCKENZIE, and Mr. LAKE, who complimented the speaker upon his statistics.

Mr. GEORGE JACKSON (Plymouth) then read a paper on

The Etiology of Auditory Meatal Exostoses,

dividing the cases into those that entirely blocked the meatus, those which did sc [illegible] caused a slight narrowing [illegible] remarks by a specimen o [illegible] caused complete occlusion and in which the patient's bone conduction was perfect, but whose aerial conduction power was one-twentieth of the normal. After removal the hearing improved for air conduction to one-half of the normal. He thought that if such growths did not materially interfere with discharge or with aerial conduction they might be neglected. Such conditions were not common, for out of 3000 cases of ear disease in the report of the Devon and Cornwall Hospital only 11 had been recorded, and of these only two required operation. He discussed their etiology, but could not arrive at any definite conclusion. They certainly generally occurred in connexion with exposure to sea-water, and he gave the results of some e [illegible] support of [illegible] quoted ma [illegible] media. Th [illegible] generally sessile.

In the discussion following Dr. H. JONES referred to a case that was bilateral, and upon which he had operated, in which there was no improvement of hearing, in which it was very difficult to find the membrane on the left side, and in which it was absent on the right.

Dr. DAN MCKENZIE (London) read a paper of considerable interest, and one showing a large amount of clinical investigation, on

The Clinical Value of the Labyrinthine Nystagmus Tests.

He included in his results many different diseases of the ear, in nearly all of which some labyrinthine trouble was suspected. The method consisted in estimating the time necessary to produce nystagmus by the application of certain fixed temperatures to the external surface of the membrana tympani. Water at two temperatures was used (so-called hot and cold tests), the relative temperatures being about 42° C. and from 22° to 24° C. The tension upon the drum was practically constant, being produced by a fixed head of water. The factors taken into account were the time necessary to produce nystagmus, the particular character of the eye movements produced, and any associated phenomena. He found that in health nystagmus appeared in from 20 to 40 seconds; in hyper-excitable states of the vestibular system it occurred in from five to 15 seconds; while in cases of diminished excitability the time was from 50 to 120 seconds, and when the labyrinth was not responsive no reaction followed. Vertigo was generally first experienced, its severity usually varying inversely to the induction period. In all cases both ears were compared before coming to any decision, and any nystagmus produced by testing one ear was allowed to pass away before making any tests upon the other ear. He found the reactions in cases of simple chronic middle-ear catarrh to be those of health, while in oto-sclerosis the results were widely different, and the reaction bore no relationship to the degree of deafness. Occupation deafness was referred to, but the numbers examined were too few to enable any conclusive results to be established. Three cases of hysterical deafness showed that the vestibular sense was impaired in proportion to the severity of the deafness. All the cases of neurasthenic deafness gave the reaction of hyper-excitability of the nervous mechanism, the induction period being very short. This contrasted markedly with cases of perceptive deafness. He found that the cochlear function was not always destroyed *pari passu* with the vestibular, and this was so in syphilis of the labyrinth. These tests he considered important in the large group of suppurative conditions, as they should show the extent to which the disease had progressed, and he found that in chronic uncomplicated suppuration of the middle ear, and in cases of acute mastoiditis, the reactions were normal or only slightly exaggerated, but in cases of circumscribed labyrinthitis the vestibular sense was impaired, whilst impairment was still further increased after the simple radical mastoid operation, possibly either because the resulting scar tissue in the neighbourhood interfered with the transmission of heat, or that the inflammation had destroyed the special sense-organ in the ampullæ. He gave many clinical results and from these inferred that in many conditions of ear disease the reactions were not sufficiently uniform to be of pathognomonic value, yet when taken into consideration along with other symptoms, as for example the hearing and the rotation tests, they were of assistance.

Dr. H S. BARWELL (London), in the discussion following, hoped that the investigations would be continued, especially upon normal individuals.

Dr. BARR thought that cold water applied to the membrana tympani was generally injurious.

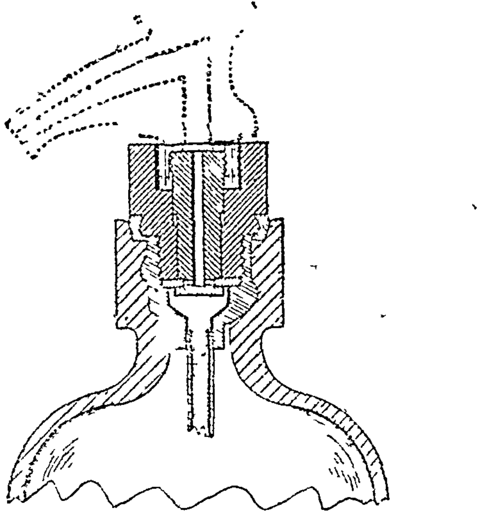
Dr. MCKENZIE, in replying, stated that the time of application of the cold water was too short to have any harmful effects and that no sickness or faintness had followed.

THE ANNUAL EXHIBITION.

(Continued from p. 400.)

IV.—SANITARY APPLIANCES.

THOUGH comparatively few in number, the exhibits under this head were interesting in variety, and comprised filters, mineral water apparatus, and disinfectants. A number of various forms of filters was shown on the stall of Messrs. Slack and Brownlow of Abbey Hey, Gorton, near Manchester; but attention was directed in particular to the Brownlow germ filter, constructed of porous porcelain, and to a modification of it for hospital use which provides a supply of hot or cold sterile water. Messrs. H. and T. Kirby and Co. of 14, Newman-street, London, W., exhibited their "ideal valve" feeder which we have already described as a useful hygienic appliance for the nursery. The valve is of solid glass and indiarubber collars and washers are properly dispensed with. An attractive series of sanitary polishes and accessories formed the feature of the exhibit of Messrs. Ronuk, Limited, of 86, York-road, Lambeth, London, S.E. Here were specimens of model floors in various woods polished by the Ronuk improved sanitary methods and also samples of liquid and concentrated Ronuk for hospital use. The Jeyes' Sanitary Compounds Company, Limited, of 64, Cannon-street, London, E.C., had a large stall literally packed with their disinfectant preparations, notable amongst which were those containing the non-toxic germicide "cyllin." The Hygienic Syphon Company Limited, of 20, Bucklersbury, London, E.C., exhibited their hygienic syphon which secures the acme of cleanliness as far as the storage and preservation of aerated water in a syphon are concerned. The accompanying diagram will help to explain its construction.



The Hygienic Syphon.

The porcelain spout (shown in dotted lines) is detachable and when the syphon is not in use a porcelain stopper may take its place (as, for example, in transit). By simply pressing the spout when in position a rubber valve below is pushed beyond a series of perforations in the delivery tube through which the water then passes. Amongst the advantages of the syphon are (1) simplicity of parts by which the most scrupulous cleanliness may be secured apart altogether from the impossibility of metallic contamination; (2) an easily cleaned reservoir; and (3) the detachable spout serves also as a key, so that the water can be reserved for private use. The use of the word "hygienic" in the name of this syphon is completely warranted. The Sanitas Company, Limited, of Limehouse, London, E., showed a number of disinfectant fluids, powders, and soaps, besides some apparatus for the convenient use of sulphur dioxide, formaldehyde, &c., for practical disinfection. The exhibit included a vaporiser to be used with "bactox" in certain respiratory diseases. At the stall of Messrs. B. Kuhn and Co., of 16, Rood-lane, London, E.C., the applications of chinosol for antiseptic and disinfectant deodorising purposes found illustration in a series of interesting preparations.

V.—MINERAL WATERS, BEVERAGES, ETC.

Non-alcoholic beverages were a decided feature of the exhibition and it may be noted that Belfast enjoys a reputation for the purity and excellence of the mineral waters manufactured there. It has been said, indeed, that the cause of temperance in the city has been materially helped by the attractive quality of its "dry" ginger ale which happens to be a speciality of the place. The artesian well water-supply is remarkably pure and particularly suitable for the preparation of aerated beverages. Every conceivable kind of aerated water was to be found in the stall of

Messrs. Grattan and Co., Limited, of Belfast, who in spite of the purity of the water in its natural state go further and sterilise it previous to carbonating. Amongst special beverages *may be mentioned their "crown soda"* ginger ale (*sans sucre*), lithia, potash, quinine, and piperazine waters. Messrs. Ingram and Royle, of East Paul's Wharf, 26, Upper Thames-street, London, E.C., had a most complete representation of natural mineral waters, including Contrexéville, Æsculap, Vichy (Célestins, Grande-Grille, and Hôpital sources), whilst specimens also of the dry natural Carlsbad sprudel-salt were shown. The corporation of Bath drew the attention of the visitors to the merits of the historic thermal springs of that city by a series of photographs and medical reports and other literature. It is satisfactory to learn that British people are beginning to realise that in the thermal waters of Bath they possess a medical asset unrivalled by any spa abroad, including [illegible] highly extolled waters abroad. The environment of Buxton is notoriously healthy, and the authorities may be congratulated on giving considerable attention to the social requirements of a bath station, as well as to advanced balneotherapeutic methods. Messrs. Findlater and Co., London Bridge Corner, London, S.E., showed a number of medicinal waters of foreign origin, including the aperient sulphated waters of Carabana, Spain, the alkaline waters of Ems, the arsenical waters of Levico, the iron waters of Schwalbach, and the alkaline waters of Wildungen. The representatives of the Apollinaris Company of 4, Stratford-place, Oxford-street, London, W., explained the advantages of Apollinaris water in large stoneware bottles. The water keeps cool in these bottles, and competes with other mineral waters in regard to price. As is well known, the degree of alkalinity of Apollinaris water is considerably higher than other mineral waters, and hence its value in catarrhal affections. The exhibit included the natural aperient water "apenta," which is now well known as a convenient and effective bitter purgative. The attractions of the Royal Leamington Spa were illustrated in a series of photographs, guides, and publications, and it was made evident that the authorities there are leaving no stone unturned to bring this health resort into line with modern requirements. A well-known effective yet mild bitter purgative saline water is Friedrichshall, specimens of which were shown by Messrs. C. Oppel and Co., of 10 and 12, Milton-street, London, E.C. Grape juice appears to be coming into favour as a beverage mixed with plain or aerated water, while some have employed *it for the* "grape cure." *Messrs.* Schweppes, Limited, of 49, Pall Mall, London, S W., exhibited their "Vindevie," which was recently reported upon in our columns. It is a sterilised grape juice with pleasant slightly acid flavour. There were also exhibited samples of "proset," dry and sweet, a non-alcoholic beverage with delicate fruity flavour, and dry ginger ale, which is said to help the "drink patient" out of his habit. Another excellent grape juice was exhibited by the Grape Juice Company, Limited, of 7, Great Tower-street, London, E.C. Cider was well represented by Messrs W. Gaymer and Son, of Attleborough, Norfolk, who exhibited amongst other specimens some "dry" varieties, sound and of excellent flavour, and free from acidity. Bendle's meat port (Bendle, Limited, 41, Seething-lane, London, E C.) was the only wine of the kind in the exhibition. As our analysis has shown, it is sharply distinguished from other wines by the fact that it contains actual nutritive materials in the shape of proteins.

VI.—PUBLICATIONS.

Stalls containing books of reference on medical subjects formed a relief from the spaces occupied with foods, drugs, surgical appliances, &c. Amongst the well-known publishers exhibiting recent additions to medical literature were Messrs. John Wright and Sons, Limited, of Bristol; the British Medical Association as publishers of the *British Medical Journal*, 429, Strand, London; Messrs. Henry Frowde and Hodder and Stoughton, Oxford; Messrs. D. Appleton and Co., 25, Bedford-street, Covent Garden, [illegible] and the Cambridge University Press; Mr. H. K. Lewis, of 136, Gower-street, London; Messrs. Rebman, Limited, of 129, [illegible] W.C.; W. B. Saunders Comp[illegible] Covent Garden, London, W.C. [illegible] of 5, Henrietta-street, Cover[illegible]

VII.—MISCELLANEOUS.

There were few exhibits this year coming under this section. In it may be mentioned a motor car by Chambers Motors, Limited, of Cuba-street Works, Belfast, designed specially for the use of medical men and described as being able to stand hard work, and economical as regards petrol consumption and running capacity; the special non-sagging bed mattresses of Messrs. John and Joseph Taunton, Limited, of Belgrave Works, Sherbourne-road, Balsall Heath, Birmingham; and the Aertex cellular clothing of the Cellular Clothing Company, of 72 and 73, Fore-street, London, E.C. In the last exhibit an interesting fabric was shown in the shape of a specially dyed red Aertex material for use in the tropics which prevents the passage of the actinic rays of the sun to the body but allows the red and orange to pass.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-eighth annual meeting of this association was held, as has already been announced in THE LANCET, on July 22nd and 23rd at the West Riding Asylum, Wakefield, and at Leeds, under the Presidency of Professor W. BEVAN-LEWIS.

The morning session of the first day was devoted to the [illegible]

The retiring President, Dr. C. A. Mercier, and his retiring coadjutors on the council having been cordially thanked, Professor Bevan-Lewis took the chair and read his address. After brief acknowledgments for the honour conferred upon him in his elevation to the presidential chair he announced as the subject of his address, The Biological Factors in Heredity. *Whilst paying a tribute of admiration* to the elaborate researches of Sir Francis Galton and Karl Pearson, and admitting the great utility of statistical studies in heredity when confined to their proper sphere, he maintained that the biological method was supremely that proper to the physician to study, and the only true method which would unravel the many problems of genetics. After dealing minutely with [illegible] he devoted special attenti[illegible] results which had been [illegible] against the accuracy [illegible] that such apparent inconsistencies were the result of misinterpretation on the part of the opponents of Mendel's teachings, that most objections had been triumphantly met, whilst others were still awaiting more elaborate inquiry on the ground of their complexity, or the very recent date when Mendelian *methods were* first applied by Bateson, de Vries, Tschermack, and Correns. With a brief reference to mutation, as taught by de Vries, and to its incompatibility with the doctrine of minute continuous variations regarded by Darwin as the groundwork upon which evolution proceeded, he indicated the foreshadowing of this doctrine of the importance of discontinuous variation by Huxley in 1861. In dealing with the fallacies of interpretation whereby the biometrician had failed to reconcile Mendelian with statistical results, he dealt with the phenomena of segregation, its failure from definitely ascertained [illegible] especially in connexion with parthenogenetic [illegible] and the probable struggle betwixt the sex[illegible] selection-mating"—as it has [illegible] fallacy were shown to [illegible] stituted "unit [illegible] coupling of such units, the inheritance of coat-colour in rabbits and mice, as worked out by Bateson, Miss Durham, and others. The more intricate combinations of unit characters and their transmission were illustrated by descriptive charts. Dominance as a biological phenomenon was then referred to as contrasted with prepotency in the Darwinian sense, and it was shown to be a non-essential factor in establishing the accuracy of Mendel's law; whilst lantern slides were shown illustrative of partial and complete dominance. Lastly, purity of type was alluded to, and the application of Mendelian formulæ to disease, so far as already worked out. Illustrations of the transmission of the predisposing factors in disease, in accordance with Mendelian facts in human heritage, were discussed, the results of recent research being shortly detailed. Mendelian methods of interpretation bearing upon nervous and mental diseases were dealt with, and the statement made that "towards such as challenge the validity of Mendel's methods and would substitute statistical inquiry in their place as the only method for unravelling the mysteries of heredity, there can be no compromise."

The President distributed the prizes gained during the year as follows: Dr. Henry Devine, Long Grove Asylum, Epsom, the Gaskell prize, consisting of £45 and a gold medal, at the same time congratulating him on his recent success in the University of London; Dr. G. H. Grills, Chester Asylum, £15 and a silver medal; Dr. Colin McDowall, Hatton Asylum, Warwick, the bronze medal and £10

On the proposition of Dr. Mercier, seconded by Dr. G. H. Savage, a hearty vote of thanks was passed to Professor Bevan-Lewis for his address, Sir James Crichton-Browne adding an eloquent tribute to the President's work in the domain of the study of insanity.

On the evening of the first day the members and their guests dined together at the Queen's Hotel, Leeds. The President was in the chair, and among those supporting him were the Bishop of Wakefield. The toast of the evening, "The Medico-Psychological Association," was proposed by the President in a speech full of most interesting reminiscences, which concluded by an extremely hopeful outlook concerning the future of psychiatry. Other toasts were "The Leeds University," "The President," and "The Visitors," in addition, of course, to the usual loyal toasts.

The proceedings on the second day were opened with a paper by Dr. Helen Boyle entitled, "An Account of an Attempt at the Early Treatment of Mental and Nervous Cases." The essayist said that during her two and a half years as a County County medical officer in East London she had been appalled at the sight of mental patients being manufactured in the rough. People who were poor, unhappy, neglected, maltreated were turned into lunatics through sheer stress. All that could be done for a poor mother of ten children after childbirth was to give her a bottle of medicine and tell her to go home and rest. No hospital would take her, as she had no organic disease, and no asylum would take her, as she was not certifiable. Much good work was done in the limits imposed by small funds by a hospital which took nervous cases early—cases which, but for timely treatment, would probably have been merged into the insane. Dr. Boyle detailed the methods of treatment, and was able to point to extremely good results. The institution admitted only women, and patients from every kind of profession had been admitted.—The paper was discussed by the President, Dr. Rayner, and Dr. Oswald.

Dr. J. R. Gilmour read a paper on the Mental Symptoms in Exophthalmic Goitre and their Treatment. He detailed with much minuteness the various symptoms, the outstanding features of which were irascibility, irritability, suspicion, and restlessness. In one case improvement suddenly set in after the administration of quinine had been commenced, and this was furthered by the administration of milk from thyroidless goats, and the latter treatment was helpful in nearly all the cases dealt with. Rest, taken in the open air, was of very great importance in Dr. Gilmour's view. A combination of bromide of patassium and belladonna was of great benefit. In cases of "tidal Graves's disease" he advocated partial thyroidectomy.—The paper was discussed by the President, Dr. G. Scott Williamson, Dr. Bower, Dr. Orr, Dr. L. D. H. Baugh, and Dr. Helen Boyle, and Dr. Gilmour replied.

Dr. Scott Williamson read a paper on the Cerebro-spinal Fluid in General Paralysis and the Nervous Lues, in which he dealt with the chemical characters of the cerebro-spinal fluid and their diagnostic importance, confirmed by a review of 78 examinations, with special reference to the syphilitic reactions of Wassermann, Porges-Meier, and others.—The contribution was discussed by the President, Dr. R. G. Rows, Dr. McRae, Dr. Gilmour, and Miss Winifred Muirhead (Glasgow), most of whom were also engaged in bacteriological work bearing on various mental states.

Dr. Scott Williamson's other paper on the Bacillus Paralyticans, a contribution which criticised the work of Ford Robertson and others on this micrococcus, was the occasion of a keen debate, in which Dr. W. Ford Robertson, Miss Muirhead, Dr. McRae, and Dr. W. H. B. Stoddart took part.—Dr. Williamson replied at some length on the points raised, but admitted that the subject was one of considerable difficulty, and there was not time for a full and adequate reply on the many points raised.

The next paper was one, prepared at short notice, by Dr. Ford Robertson, on the Experimental Production of General Paralysis. The contribution was illustrated by some striking photographs of rabbits in which various definite symptoms had been produced.—Dr. Orr said that the evidence adduced by Dr. Ford Robertson of neuro-toxicity was very striking and the work came very much into line with some work which Dr. Rows and he were doing. He reminded members that three years ago Dr. Rows and himself published the results of toxic infection of the lymph paths leading up to the spinal cord, and the method they adopted was one which eliminated the fallacy of injury to the cord—namely, putting the toxin into a small celluloid capsule and placing that under the sciatic nerve of a dog, leaving it there for a time until it was clear that the toxin had escaped from the capsule and entered the lymph paths. But to make the research complete it was necessary to trace the histological evidence of that upward passage of toxins right along the nerve and the posterior ganglion root to the cord itself. They were able to say that the bacillus of Robertson and McRae was a highly toxic body, but pending further work, upon which they were engaged, it was best to suspend ultimate judgment. Changes were produced by it in the smaller vessels, with proliferation of the adventitia. Also, the nuclei lining the endothelial spaces in all directions were proliferated, especially the posterior nerve. The most striking point in regard to the cord was the dilatation of the central canal. The ependymal cells were proliferated several deep and the neuroglial cells about the ependyma showed marked proliferation, while the nerve cells showed nucleation.

Mr. L. O. Fuller read a very interesting paper on Alcoholism, Crime, and Insanity. He pointed out that children of the poor were often in conditions in which they were given every chance of acquiring the drink habit, and among their parents tubercle and syphilis were common. He regarded post-natal environment as a very great cause of degeneracy. Though the child might not be very intellectual he was a good imitator, and copied his parents' habits with great facility. One case admitted under his care recently was that of a girl, aged 22 years, who commenced to get drunk at the age of 11 years, and both her father and mother were heavy drinkers. At the age of 14 years she adopted immoral habits, and during the last eight years she had spent her time in drink, jail, and prostitution. By their eighteenth year some girls had had one or two illegitimate children. The most scientific way of dealing with degeneracy was one which aimed at removing the causes rather than alleviating the symptoms, a great desideratum being much greater elasticity in the educational system. If a person showed relapse he should have a period of instructive detention, with a view to prevent drink habits being firmly formed; this should combine medical instruction with disciplinary methods. He strongly objected to a predetermined sentence: to the youngster it was often a hardening process, it threw him into the ranks of the unemployed and often the unemployable, and finally he became very hostile. He was not usually a lunatic and he was not wholly responsible, but he was often capable of improvement by instruction and could be taught a handicraft. A short prison instruction could not give benefit to a person who was mentally backward. He advocated the establishment of receiving houses, into which such cases as he was describing could be admitted in the first instance. He strongly objected to the fixed term of three years; there were many cases in regard to which such a sentence was unnecessary, and expressed his belief that there was much necessity for an alteration of our present system.—Dr. MERCIER, in discussing the subject, said that there were points in it with which he would agree, and others with which he did not agree; particularly he agreed in deprecating the stupidity of the fixed three years sentence. These people were sent to a reformatory, where it was felt that their condition was at any rate as much a disease as a vice, and being a disease, they were sentenced to a fixed term, in which he supposed it was anticipated their disease would be cured, and that the cure would take neither more nor less than that time. That led to what he did not hesitate to call abominations. Under the instruction of the Home Office the term "not exceeding three years" had become in practice a term of not less than three years. He had seen cases receive all the benefit they were likely to derive from reformatory treatment in six months, yet they were compelled to stay there another two and a half years, in which time they had mostly lost whatever ability to work which had remained in them. One man told him that he had forgotten the very names of the tools he used to work with when he went in. Again, when they went out there was no supervision over them, and in many cases they quickly got into the hands of the police again. And, as if to make such a sequel more likely, they were on discharge handed a sum of money which had been put by for them during their detention. Inebriates were on quite a different footing from lunatics; the former were much less certain in the matter of conduct. He did not agree that abstinence, or partial abstinence, from alcoholic drinks argued the possession of a superior power of self-control. Some people, having taken a certain, sometimes a small, quantity of alcohol turned against it and had no desire for more; others did not turn against it until they had been drinking for two or three days.—Dr. HEARDER said that in his locality the magistrates would not send a case to the reformatory unless it showed mental symptoms, but the sentence was not fixed—it ranged from one to three years. Moreover, the *cases could be discharged on licence, so that it could be* seen how they behaved themselves. And in their case the money which was put by for the patient was not handed to him, but to responsible relatives or other persons always at a distance, so that the patient had at least to get [illegible] more drink.— [illegible]d [illegible]ty that in 70 per cent. of inebriates there was a weakened power of control compared with that possessed by the majority of the community. He believed that the inebriate was a different kind of person from the drunkard.—Mr. FULLER having replied, the session closed.

PREVENTABLE BLINDNESS.

THE Committee on "Preventable Blindness," which was appointed at the International Conference on the Blind, held at Manchester in July, 1908, has recently issued the following report:—

The subject of the prevention of the disease which so frequently causes blindness in newly-born infants is one that for many years has engaged the attention of all whose work has brought them into contact with the blind. At every conference that has been held during recent years relative to the welfare of the blind, whether at home or abroad, attention has been called to the urgency for taking satisfactory measures for the checking of this disastrous cause of blindness.

The medical libraries contain a host of papers and books which have treated of this disease, and of the blindness consequent thereon. Recent English literature has been summarised in the report of the British Medical Association Committee (*British Medical Journal*, May 8th, 1909), to which reference will be made further. The gist of these papers is to the effect: 1. That more than one-third of the blindness found in British blind schools is due to this one cause—infants born with good eyes are blinded by the disease within a few days of their birth. 2. The risk of blindness is entirely preventable by prompt and efficient treatment.

To this end it is now almost universally agreed, by medical men and laymen cognisant with the subject, the disease known as the "Ophthalmia of the New-born" should be scheduled as compulsorily notifiable. And it is believed that by such action this appalling source of misery and helplessness would be checked. In spite, however, of these urgent recommendations, no action has been taken by the British public health authorities, *nor have these* authorities, so far, availed themselves of their permissive powers to make the disease compulsorily notifiable.

At the International Conference on the Blind, held in Manchester in July, 1908, it was held that no sufficient steps had been taken to give publicity to the urgency of the matter. A representative committee was therefore appointed to consider the subject fully, and to make such recommenda- [illegible]

(hon. surgeon, Leeds United Institution for the Blind and Deaf and Dumb), and Mr. N. Bishop Harman (oculist to the London County Council Blind Schools). These gentlemen were expected to advise on matters relating to the north and south of England respectively. During the sittings of this committee, another committee, instituted by the British Medical Association, has had this same matter under review. The two committees have acted upon quite independent lines, and the fact that they have arrived at similar conclusions and make virtually the same recommendations adds greatly to the weight of their recommendations.

The following are the recommendations of the committee appointed by the International Conference:—

1. That in the opinion of this committee the adoption by the public health authorities of the Early Notification of Births Act is urgent.

2. That in the opinion of this committee the disease known as the "Ophthalmia of the New-born" should be added to the list of diseases compulsorily notifiable under the powers of the Infectious Diseases (Notification) Act of 1889.

3. *That in the opinion of this committee: (a) More* definite teaching should be given to midwives on the seriousness of eye disease in children; and (*b*) they suggest that the Central Midwives' Board should issue more stringent instructions on the danger of "whites" in lying-in women.

With a view to obtaining more exact knowledge of the incidence of "blindness" in subsequent census returns, the committee recommend that the Registrar-General should be requested to define and classify "blindness" in his schedules in some such way as the following:—

1. Stone blind—i.e., the individual has no power to see the movement of fingers before the eyes.

2. Partially blind, i.e., in the case of—i. *Children.* Those who have not sufficient sight (even with the aid of glasses) to be taught in an ordinary school. ii. *Adults.* Those who have not sufficient sight (even with the aid of glasses) to earn a living by ordinary means.

In conclusion, the committee desire to emphasise the fact that the question is at the present juncture, and is likely to be in the future, of much greater importance than in the past. *For the introduction and extension of the operation of* the Employers' Liability Act is seriously affecting, and is likely to still more seriously affect, the earning powers of adult workers with defective vision.

NEW HOSPITAL FOR TORRINGTON (DEVON).—On August 4th L[illegible] G[illegible] [illegible]ew cottage hospital [illegible] a site given by th[illegible] [illegible]nd that of other local benefactors the building has been erected as a memorial. *The hospital contains surgery, consulting* room, operating theatre, matron's rooms, &c., and will pro- [illegible] eight patients. The cost of the [illegible] as all this amount has been sub- [illegible] of debt.

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1909.

Preventable Blindness.

The fact that from 30 to 40 per cent. of persons in blind institutions have lost their sight from ophthalmia neonatorum or purulent conjunctivitis of infancy is indeed lamentable, and now that renewed attention is being devoted to this preventable disease we may hope that some adequate measures will soon be adopted to remove the evil. Some years ago the matter received careful consideration by the Ophthalmological Society of the United Kingdom and certain resolutions were adopted and placed before the authorities. The comparatively small financial outlay involved in carrying out these suggestions—a matter of some £7000 odd—was held to be prohibitive, in spite of the obvious fact that the cost of education and support of those blinded by the disease immeasurably surpasses this amount. In 1907 an energetic effort was made to induce the British Medical Association to take the matter in hand. The need for this action had been conspicuously shown by Mr. Sydney Stephenson's book on "Ophthalmia Neonatorum," which gained the Association's Middlemore prize and which presented an admirable survey of what had been done in the past and of the large amount that yet remained to do in attacking the disease. As a result of the attention then directed to it a representative committee of the Association was formed, and after prolonged and exhaustive investigations a report was drawn up, and at the recent meeting at Belfast the report was discussed by the combined Obstetrical and Gynæcological and Ophthalmological Sections. It will be seen from our *résumé* of the proceedings (p. 459) that the principle of notification of the disease was approved, though the attendant difficulties in practice were fully recognised. Exception was taken, and we think rightly, to the suggestions as to treatment. In our opinion the disease is too serious and its consequences are too grave for the treatment, even in the matter of prophylaxis, to be left in the hands of unqualified people, and if it is relegated to the medical practitioner he ought to be allowed to adopt freely the methods which appear best to him.

Just before the Belfast meeting the report of a committee on preventable blindness, which was appointed at the International Conference of the Blind, held in Manchester in July, 1908, was issued (see p. 477). The similarity of the recommendations to those made by the committee of the British Medical Association shows the unanimity of opinion existing as to the best means of dealing with the difficulty. Notification is again advanced as the central feature of the plan of campaign. That it is productive of good results is shown by the example of Manchester, where a voluntary system of notification has resulted in a diminution of cases by 40 per cent. From another part of the country comes a report showing the awakening of public conscience to the continuance o an evil which is acknowledged to be preventable and mus be considered consequently a scandal to our civilisation In Staffordshire an influential meeting of mayors, chairmen of urban district councils, town clerks, and medical officer of health was recently held to discuss the prevention o ophthalmia neonatorum. It was presided over by the Earl o Harrowby, who in the course of his speech gave a concrete example of the financial loss due to those disabled by blindness early in life. The cost of educating a blind child up to the age of 18 years without teaching him a trade is £500, whereas the cost of educating a full-sighted boy for the nine years he was at school was only about £30. A simple calculation shows that £15,980 are wasted in Staffordshire alone in educating children blind through neglect. At this meeting notification of the disease was also advocated.

There can be no doubt, in our opinion, that notification is the first step which should be universally adopted. Another preliminary is that of extending the knowledge of the extreme gravity of the disease amongst those likely to come in contact with it. To this end the Central Midwives Board has drawn up a leaflet of instruction which will be distributed to midwives.[1] These are steps quite in the right direction; but it must be recognised that they are preliminaries only, and useless unless some scheme is devised for dealing with the cases by qualified practitioners with the greatest promptitude as soon as they come under observation. And here again comes in the pecuniary question of ways and means for the preservation of the national health—a question which is coming so much to the fore in regard to the medical treatment of school children. It is incumbent upon the medical profession to bring all its influence to bear upon the State for the prevention of such terrible disabilities as ophthalmia neonatorum inflicts upon thousands of helpless infants, but it is the duty of the State to provide that the practitioners who act as the trustees of the children's eyesight shall be properly remunerated for fulfilling the active responsibilities which that trust will entail.

◆

Preventive Medicine and the Lower Animals.

Those who can recall the battles which raged around the "Origin of Species" and the "Descent of Man" will not need to be reminded that the human being does not readily relinquish his supremacy or share with others that which he believes to be his natural prerogative. And even when man felt constrained by the force of evidence to admit his biological associations he did not easily accept the inference that he might have to share with the lower animals the heritage of certain diseases. His own maladies were clinically so unlike those of the lower animals that he was inclined to use this fact as an argument against rather than in favour of the doctrine of evolution But time has altered our attitude and epidemiologists are beginning now to wonder whether the clue to much that is still unexplained in pathology may not be and the laws of parasitology. It was only when we turned our gaze from the human subject to the insecta that the mysteries of malaria and yellow fever faded away; and similarly when we examined the life history of the goat the difficulties as regards Malta fever largely disappeared, and by studying plague in the rat and in the flea much in the malady as it attacks human beings became explicable. Thus it comes about that the annual report of Mr. STEWART STOCKMAN, chief veterinary officer of the Board of Agriculture and Fisheries, has an interest for the epidemiologist —an interest which should increase year by year as the interdependence of human and animal diseases becomes more fully appreciated.

---

[1] The Lancet, August 7th, p 409.

Although the foot and mouth disease of cattle does not in these days give rise to much recognised disturbance in man, it is well known that the milk from cows suffering from this malady may produce, especially in children, an illness attended with aphthous stomatitis, swelling of the tongue, and fœtor of the breath, or, on some occasions, severe tonsillitis. It is therefore reassuring to learn from Mr. STOCKMAN'S report of the prompt measures which were taken in an outbreak of this disease in Scotland—the first for 15 years. The initial outbreak occurred in two cowsheds, and all the cattle therein, together with those on immediately adjoining premises which were still free from the disease, were promptly slaughtered. Of the 111 animals on the actually infected premises only two cows and one calf had escaped infection up to the time of slaughter. But the infectivity of this disease seems a remarkable one and, notwithstanding the wholesale slaughter, the malady was transferred to other premises about three-quarters of a mile distant, which the owner had taken for the purpose of carrying on his business, and it was impossible to explain how the disease had been carried since none of the attendants had suffered from the malady nor had any manure been transported from the old to the new premises. But as an illustration of the disease-carrying capacity of manure it may be mentioned that the malady in question was transferred to another set of premises by soakage of drainage from a manure heap through the intervening wall. These three outbreaks involved the slaughter of 148 bovine animals on infected premises and 96 on premises dangerously situated Th[illegible] have arisen from a small [illegible] infected country, and Mr. STOCKMAN points out that the history of the epidemic renders it necessary to revise current views as to retention of virulence on the part of the virus of foot and mouth disease, as, contrary to what was formerly believed, it seems that in cool weather virulence inside a bale of hay may be retained for from three to four months.

The facts in the story of glanders serve, like the study of exclusively human diseases—if there are any—to show how the prevalence of any given malady may be immediately increased by searching for unrecognised cases. It was found in the case of glanders that the more frequent application of the mallein test in horses in contact with a declared case materially increased the number of horses per outbreak as compared with previous years. Apparently the chief difficulty in the control of glanders what animals are to be regarded as having been in contact with infection. This, in Mr. STOCKMAN'S view, is a much more serious matter than the fact that the mallein test does not reveal the disease during the incubation period, and that therefore a second test in invaded stables becomes necessary so as to detect these cases. There were in 1908 as many as 2433 horses found to be infected with glanders, and we have been wondering whether cases amongst human beings are sought out as thoroughly as amongst cattle Apparently cases in men are more numerous than is commonly believed. In connexion with anthrax Mr. STOCKMAN narrates a case of the introduction of this disease through the medium of bone manure which had been applied to a field of grass which was afterwards kept free from animals for nearly a year, during which a crop of hay was removed from it. Nine cows were then introduced for grazing purposes and three died from anthrax—a most instructive story.

The expense of transporting European pedigree cattle to the Transvaal, where they have either to be kept in stables or incur the imminent risk of contracting Texas fever by being pastured with indigenous cattle, has led to the Veterinary Department of the Board of Agriculture, in collaboration with similar departments of the Transvaal and East African Protectorate, undertaking inoculation experiments against this disease, the animals after inoculation being sent to the Colonies and pastured on farms infected with the disease in question. It is thought that if these experiments prove successful a considerable stimulus will be given to the export trade of pedigree cattle In connexion with this work Mr. STOCKMAN has, in collaboration with SIR JOHN MCFADYEAN, carried out some investigations into red-water fever in England, and he has been able to show that the blood of animals suffering or recovering from English red-water fever will infect other susceptible cattle after an incubation period of from six to ten days, the characteristic parasite, Piroplasma bigeminum, being found in the blood corpuscles, in some cases there being red colouration of the urine. *But in connexion with this* latter symptom Mr. STOCKMAN points out that although red urine was the circumstance which gave the disease one of its names, red-water fever, this manifestation is only apparent in perhaps the minority of cases, and consequently it is preferable to call the disease piroplasmosis. Mr STOCKMAN has also made some instructive investigations as to the part played in England by ticks in relation to English red-water fever, and although the Ixodes ricinus and the Hæmaphysalis punctata are both, he thinks, capable of carrying the parasites which cause the disease, he has *only so far obtained experimental* proof relative to the latter. These ticks, after engorgement upon infected and recovered animals, were kept in the laboratory until they produced progeny, and the larvæ were then allowed to suck healthy animals. Larvæ from mothers which had sucked infected animals yielded negative results, as also did nymphæ which had sucked infected animals as larvæ. But adults which had sucked as nymphæ animals with red-water fever gave the disease to the next bovine host. There can be no doubt therefore, as Mr. STOCKMAN states, that the red-water fever of England is a piroplasmosis which is inoculable and which spreads from animal to animal by ticks. It has also been found that the seasonal prevalence of red-water fever in this country corresponds with that of the greatest prevalence of adult ticks. Mr. STOCKMAN finally furnishes some useful advice as to the prevention of red-water fever, whether by inoculation, by the reduction of the number of ticks by dipping, by keeping cattle off the pastures for a time, or by stocking the pastures with sheep, which animals are not susceptible to red-water fever, but which attract the ticks. This work on the part of the Veterinary Department of the Board of Agriculture and Fisheries is of much value, and we shall look forward to an extension of it.

The Report of the Royal Commission on Whisky and other Potable Spirits.

WHATEVER may be the opinion of the liquor trade and of the public of the findings contained in the final report of the Royal Commission on Whisky and other Potable Spirits there can be no question of the thoroughness with which the Commissioners have attacked the numerous difficult points which such an inquiry was bound to bring before them. And yet as the outcome of their long deliberations the position is left much where it was. The present report, in fact, goes very little further than the conclusions arrived at by the Select Committee on British and Foreign Spirits which was appointed by the House of Commons in 1890, when almost every one of the questions considered by the present Commission was submitted to the Committee and reported upon by it. Lord JAMES of HEREFORD and his distinguished colleagues indeed express their conviction of the correctness of the conclusions of this Committee. There will therefore be some disappointment experienced by those who had hoped to find in the new report suggestions regarding fresh legislation upon the subject, or the inauguration perhaps of a new system of control by which the quality of the supply of potable spirits could be improved. There are practically no recommendations of the kind in the Blue-book, although throughout the report the Commissioners generally express concurrence with the findings of the 1890 Committee, a concurrence which gives, perhaps, a species of strength to their views.

In the opinion of the Commissioners it is not desirable, either in the interests of the trade or of the public, to enforce certain standards, to insist upon exact definitions or upon the restriction of particular materials in regard to the manufacture of potable spirits, and all propositions towards these ends, around which so much discussion has taken place, fall to the ground. The Commissioners refuse to believe that there is any importance attached to the question whether whisky is pot or patent still, and the value of whisky in the treatment of disease depends, they hold, essentially on the ethylic alcohol. Accordingly, they are unable to recommend that the use of the word "whisky" should be restricted to spirit manufactured by the pot-still process, and their conclusion is that whisky may be defined as "a spirit obtained by distillation from a mash of cereal grains saccharified by the diastase of malt." Scotch whisky is defined as whisky distilled in Scotland, and Irish whisky as whisky distilled in Ireland. Broad as this definition is, it obviously, and as we think very properly, excludes the use of such materials as potatoes, beet, and molasses. In regard to brandy, the Commissioners practically adopt the definition of the British Pharmacopœia, their conclusion being that the term "brandy" is applicable to a potable spirit manufactured from fermented grape-juice and from no other materials. The compounded spirit, however, known as British brandy should in their opinion be still entitled to the name. This last is a concession to trading interests, which throughout have been considered. It is further concluded that the application of the term "brandy" in this country cannot be controlled by the nature of the apparatus or process used in the distillation of the spirit. Here, again, the claims of the pot and patent still are put upon a common level, and more than once the Commissioners dismiss any suggestion that pot-still spirit is superior for any purpose to patent-still spirit. It may be doubted whether the view will meet with general acceptance that the alcohol and the alcohol alone accounts for all the results of prescribing a potable spirit. The popular view again that potable spirits are more wholesome for being matured by age will, we imagine, die hard, in spite of the Commissioners' statement that they were unable to obtain actual proof that such was the case. Practical experience, which for some definite reason decides at one time in favour of the use of brandy and at another in favour of whisky, is surely based on something more tangible than mere flavour. Those who use spirituous drinks are aware that whisky, brandy, and rum are different in their physiological effects. There is much here that is as yet beyond the ken of chemistry or physiology, but it is rash to conclude, we think, that all the effects of a potable spirit are due simply to alcohol.

The Commissioners by no means profess, however, that the question has reached finality as a result of their very careful inquiry, for they suggest, we are glad to see, the introduction of a statutory provision by which a magistrate can receive the assistance of two assessors, being persons of practical or scientific knowledge of the matters involved, to sit with and advise him in cases where the nature of a potable spirit is under consideration. It may also be desirable, they think, to form under authority a panel from which such assessors may be selected. Lastly, they refer to the question of forming a committee of skilled persons under Governmental authority who might assist in mitigating some of the difficulties of the subject, by advising on technical questions which affect both the administration of the Sale of Food and Drugs Acts by local authorities and the practice of public analysts. In our opinion this is one of the most important matters to which the Commissioners have drawn attention. Repeatedly in these columns we have urged the appointment of a court of reference composed of scientific authorities who would be competent to deal with the technical questions, of which the examination of whisky and other potable spirits is an example, and which so constantly arise in the administration of our laws against adulteration.

Annotations.

"Ne quid nimis."

THE RATIONAL PUERPERIUM.

As long ago as the year 1773 White of Manchester urged that women should be allowed to get up early after their confinements. In 1899 Kustner revived this idea and recommended that puerperal women should be encouraged to get out of bed during the first few days of the puerperium. In a paper recently read before the Edinburgh Obstetrical Society[1] Dr. F. W. N. Haultain, from an experience of 100 cases, put forward a plea for what he termed the rational treatment of the puerperium. The mode of management which he recommended was that the woman be encouraged to sit up in bed to meals on the second day, and subsequently as soon as she felt inclined that she be allowed to leave her bed and sit up for an hour. On the third and fourth day two hours were to be spent out of bed morning and evening, and the fifth day was to be practically spent out of bed altogether with the exception of a few hours' rest in the afternoon. Under this treatment his patients left the hospital on the tenth day. Of 100 cases treated in this way the morbidity (i.e., of which a temperature over 100° F. or a pulse-rate of over 90 for 12 consecutive hours were taken as the signs) was represented by three. Examination on the day of leaving the hospital showed the pelvic organs to be normal except in two cases where a slight retroversion of the uterus was found. In 48 of the cases examined six weeks or later involution was good, and the position of the uterus was normal except in the two cases mentioned. Dr. Haultain maintains that labour is not a disease and that the puerperium cannot be considered a convalescence. He believes that involution is influenced mainly by the circulation, and exercise of the abdominal muscles will improve their tone, accelerate the abdominal circulation, and among other advantages diminish constipation. The position of the patient can have but little influence on the occurrence of septic inflammation or upon involution, and the erect posture is less likely to produce displacements of the uterus than the dorsal position. In the same way he thinks that early rising will tend rather to diminish than to increase the chances of the occurrence of phlebitis and embolism. The blood of a puerperal woman is highly fibrinous, and to prevent coagulation the circulation should be stimulated, and this is most readily done by muscular exertion. Most of the speakers who took part in the discussion at Edinburgh were not entirely convinced by the arguments brought forward. The danger of backward displacements was thought to be considerably greater than the figures quoted in the paper showed, and Dr. J. W. Ballantyne pointed out that among the Javanese, who were compelled by custom to rise for a short time during the first day and move about the house, prolapse was exceedingly common and embolism frequent. Although it may be true, as Dr. Haultain maintains, that the normal puerperium is not a convalescence from disease, yet it may well be regarded as a convalescence from the troubles and often marked trials of pregnancy. Further than this, in a large majority of women the rest in bed, even if it be only for ten days, has a most beneficial effect upon their general health. That it is possible without any serious risk of injury to make a woman get up on the first few days following her confinement is quite true, but that it is expedient is very doubtful. We grant that fortunate results may be met with in a small series of cases, such as those recorded by Dr. Haultain, but the adoption of this method of treatment on the large scale would, we feel sure, lead to a number [illegible] It is interesting to have a [illegible] fact that women can get up within a short time of their confinements and suffer no harm, as indeed a great many among the poor do at the present time, but we do not think that it has been proved that such a procedure is desirable for the majority.

THE AMELIORATION OF LIFE FOR CHILDREN.

THAT the systematic medical inspection of children in elementary schools would lead to the necessity of providing for the treatment of the large number who would be found to be physically defective was a conclusion that could be foreseen from the time when this great social measure was first mooted. Our readers are aware of the practical difficulties that have arisen in devising a scheme for the systematic treatment of many thousands of diseased children which shall not leave any child uncared for, shall neither press too hardly upon poor parents nor yet undermine their proper sense of responsibility, and shall be equitable to the ratepayers and, at the same time, to the medical practitioners who will be responsible for the children's treatment. One thing is quite certain. Whatever be the amount of existing disease which has to be grappled with, the future watchword of this national movement must be "Prevention" rather than "Cure," not only because cure is in a great many cases impossible of attainment, but also because in the long run prevention is the cheaper way of rearing a healthy generation. And the business of prevention cannot be confined to the school, for no amount of sanitary supervision of class-rooms and playgrounds, or of hygienic instruction imparted to the children can be of any avail while dirt, squalor, and penury are the conditions which dominate their home life. What is wanted is the general amelioration of life for large numbers of children to whom we are imparting "education" which they are totally unable to assimilate, and which in too many instances affords a cruel commentary upon the facts of existence as they know them. In our last issue we published a paper read at the recent Leeds Health Congress by Dr. James R. Kaye, medical officer to the West Riding county council, to which he gave the suggestive title, "Ameliorative Measures Indicated by School Medical Inspection," and in which he put forward a plan by which the general amelioration of life in its broadest sense for the children of the masses, both by improvement of home conditions and by prevention of disease, may be made something more than a pious phrase on the lips of drawing-room reformers. After very properly remarking that the primary object of inspecting school children was not to compile statistical and anthropological figures, but to put the children in the way of becoming healthy and useful men and women, Dr. Kaye laid down a scheme by which the proper help may be given to each individual child. It consists in the formation of a "Care of Children Committee" in each district, having the district education subcommittee as the nucleus, to which will be added special workers each entrusted with the personal supervision of a certain number of children, and directly responsible to the committee for their care and progress. The chief sphere of activity of these missionaries of health would be in the children's own homes. They would do their best to see that the parents took proper advantage of the expert advice given by the medical officers who had inspected the defective children, or who had given advice as to treatment. They would use their influence to make the homes brighter and cleaner—a matter in which, to achieve success, zeal and righteous indignation must assuredly be tempered with tact and sympathy; and they would bring to the notice of local charitable persons or agencies cases worthy of assistance, and in general concentrate their special efforts on the amelioration of such conditions as are known to be favourable to the development of disease. The principle of voluntary coöperation with specially appointed committees for the safeguard of the public health is not quite new, for it will be remembered that the Majority Report of the recent Poor-law Commission recommended the formation of medical assistance committees which were to help the proposed "Public Assistance Authorities" and to include amongst their numbers voluntary workers in the cause of the public health. If Dr. Kaye's scheme is to take effect on any wide scale—and we shall be glad to hear that it is being given a trial outside Yorkshire—we are inclined to think that the special workers will have to be paid. Some doubt may be felt as to whether they should all actually have seats on the care committees, of which they will be in some sense the servants, but they should certainly have representation on those bodies. But this is an administrative matter which we need not now discuss, for we have fulfilled our purpose in commending Dr. Kaye's scheme of amelioration to the careful study of all who are interested in the final solution of the problem of the children's health.

[1] THE LANCET, July 31st, 1909, p. 297.

THE IBERIAN TYPE AND DISEASE.

MEDICAL geography is a science in embryo, but already good work has been done in the direction of estimating the incidence of disease in particular districts. It would be of interest if in future medical topographers would note whether disease runs in families of a particular type in the districts under examination. Is cancer, for instance, a disease particularly of "the old black breed," the Iberian or brunettist peasantry who descend, in all probability, from a pre-Celtic race and are everywhere to be found side by side with fair-haired and fair-complexioned Saxons? In certain towns, such as Exeter in the far south-west and Thurso in the far north, fair and dark types are constantly found in sharp contrast, for fair and dark have lived immemorially juxtaposed in both places. In Exeter there was a Cornish or Celtic quarter of the city well on into the Middle Ages. Here, then, the inquiry is easily conducted, but there are more rural districts where fair and dark continue in well-defined separate existence. We have in view now the narrow belt of cultivated land, some three miles wide, which lies between the virgin heaths of the New Forest and the shore of Christchurch Bay. Here philology suggests that certain families belong to the Jutic or Saxon invasion of the early ages, while certain place names point to Celtic or pre-Celtic patches of population having lingered on in secluded corners, as they are known to have lingered in the Fens and elsewhere. A prevailing clan at Highcliffe is Frampton. (*Query*, "fram," in Scandinavian, "forward" or a "ship"? Whence we get "Fram-tun," "forward-settlement," or "ship-settlement.") A few miles to the westward Hengistbury Head marks the site of a very early Saxon or Jutic "burg," whence settlers may have pushed forth along the neighbouring shores. In all this belt of land to the south of the forest the local type is often remarkably blonde, in the case of the children certainly. At Bransgore, which juts with its woods across the Forest boundary to the north, the Iberian types are found. Now "Bran" is a Celtic name, and one is tempted to believe that Brans-"gore" means the wedge of land where Bran, an early Briton, left descendants whose type remains. The Iberian, or very dark type, is common all over Hampshire. In some remote villages, as at Bosham in the neighbouring county, one might fancy oneself in the West of Ireland, to judge by the appearance of the dark-haired and blue- or grey-eyed inhabitants. In his interesting natural history study of Hampshire and the New Forest, Mr. Hudson has much to say of the Forest Iberians. In many manifestly English peasant families, he avers, he has found one raven-tressed ivory-complexioned child, usually of intelligence superior to that of its brothers and sisters, whom he holds to be a cast-back to a prehistoric type. On the other hand, Gilbert White, a Hampshire man, thought that all Whites were Gytes, descendants of Gytas or Jutes. The point of these remarks, however, is not meant to be philological. What the medical profession would like to know, and what members of that profession might be interested to ascertain, is how far do certain diseases attack one or other racial type by preference.

THE SIXTEENTH INTERNATIONAL MEDICAL CONGRESS AT BUDAPEST: THE ABSTENTION OF ROUMANIA.

THE preliminary arrangements of the forthcoming International Medical Congress, which will take place at Budapest between August 29th and Sept. 4th, have now been completed; and the preparation of the programme of the various fêtes and official functions which will take place in connexion with it is at present engaging the attention of the committee, which is working hard to make this Congress at least as memorable as its predecessors. The accommodation of members of the Congress has been made a matter of especial care, and a number of rooms in hotels and lodging-houses have been reserved by the Central Travelling Ticket Office (V. Vigadó-tér 1, Budapest) on behalf of those who intend to be present but have not yet enrolled themselves as members. At the same time, it will be well for all such people to write and signify their intention of attending, enclosing their subscriptions, in order that they may profit by the reduced fares and other advantages offered to members of the Congress by the various railway and steamship companies serving Budapest. Those desirous of obtaining further information should communicate with the Secretary-General of the Congress at VIII Esterházy-utca, 7, Budapest, until August 19th, and at VIII. Museum-körút, 6/8, Budapest, after that date. In England we have for many years succeeded fairly well in keeping professional questions out of the arena of party strife in which rival politicians and sectarians contend. This has been fortunate for all concerned, both for the patient and the practitioner, because medical science is from its nature something apart from the various artificial distinctions which society has created for itself. In ague or syphilis the Whig and the Tory take the same kind of physic; in certain diseases of nerve or muscle a leading light in Calvinism resorts to galvanism just as a latitudinarian would do. It therefore seems to us truly unfortunate that a kind of schism due to political causes has arisen in connexion with the approaching International Congress of Medicine in Budapest. The nature of the trouble is disclosed in a circular which has been forwarded to us by "Le Comité National Roumain pour la Participation au XVI-ème Congrès International de Medecine." The circular is signed by 27 professors in Jassy and Bucharest, the list being headed by Dr. Thomas Jonnesco, dean of the Faculty of Medicine in Bucharest. It states that the medical men of Roumania have decided not to take part in the International Congress of Medicine to be held in Budapest because a Roumanian lady married to a Hungarian Member of Parliament had been sentenced to imprisonment by a Hungarian court of law, her alleged offence being that she had told some Roumanian children that it was for them a right and a duty to cultivate their national language. *Everybody will admit* that the lady was right and that the Hungarian judge or magistrate was wrong; the sentence, moreover, was not carried into effect owing to the medical men, and inducing them to reconsider their decision.

MUNIFICENT GIFT FOR CANCER RESEARCH.

THE late Mr. Harry Barnato bequeathed a sum of money, amounting to a quarter of a million sterling, for the establishment of a charity in memory of his brother, Mr. Barney Barnato, and of his nephew, Mr. Woolf Joel, both of whom died before him. It was the desire of the testator that the institution when founded should be devoted mainly to research work. We therefore cordially welcome the announcement that the trustees, Mr. S. B. Joel, Mr. J. B. Joel, and Mr. S. G. Asher, have decided upon applying the bequest to the building and endowment of an institution for the study and treatment of cancer. We heartily congratulate these gentlemen in their choice, and we believe that no better employment of the munificent gift could have been adopted. The new establishment will be administered, except as regards its finance, in connexion with the Middlesex Hospital. Those connected with that hospital have had a vast experience in dealing with patients suffering from cancer, and a most painstaking research by competent observers is being carried on within the special "cancer wing" connected with the hospital. Fortunately a site was available adjoining the hospital and this has been duly acquired. It is proposed to erect a building containing 50 beds and a research laboratory, but no definite plans have yet been made. An increase of facilities for investigation into the nature of, and treatment of, cancer, under the supervision of the authorities of a great hospital constitutes a grand addition to our scientific and humane resources, and the trustees of the Barnato bequest may feel assured that the fullest and best use will be made of the increased opportunities afforded for research work, while the unfortunate victims of the disease will largely benefit, inasmuch as many more beds will be available for their assistance. It is also right to mention that the Middlesex Hospital authorities will not be relieved in any way from their present responsibilities in connexion with the main hospital or with the special cancer wing. The Barnato fund will be entirely devoted to the building and endowment of the new buildings. In this way it is hoped and believed that medical science will receive most valuable assistance, for it is only by constant and prolonged investigations that advance can be made in the prevention and treatment of a disease the exact nature of which so far baffles inquiry.

A PERMANENT APPENDICULO-VESICAL FISTULA.

IN the *Journal of the American Medical Association* of April 3rd Dr. R. Cadwallader reported a very rare sequel of appendicitis. A girl, aged eight years, suffered from nocturnal incontinence of urine which would not yield to the usual remedies. At the age of 12 it was noticed that mucus and pus were passed in the urine with pain. These symptoms were more marked when the bowels were loose. At times she suffered also from colicky pain, which never confined her to bed or suggested appendicitis. At the age of 17 years fæcal matter was observed in the urine from time to time. This matter usually took the form of seeds of fruit, husks of grain, mucus, and brown débris, and was not always of a fæcal odour. At times gas of a decidedly fæcal odour was passed with the urine. The patient thought that at times she passed urine by the bowel. She came under Dr. Cadwallader's care at the age of 20 years. He tried to establish beyond doubt the existence of a vesico-intestinal fistula. Inflation of the bladder and of the intestines was performed without success. Iron given by the mouth could not be found in the urine nor did methylene given by the mouth escape by the rectum. For days nothing appeared in the urine, and then blackberry seeds, pearl barley, and striped muscle would appear according to the diet. The cystoscope showed no inflammation of the bladder, but on the fundus was a dark patch, at one spot on the border of which was some inflammatory tissue. Laparotomy was performed. A large adhesion was found between the ileum and the fundus of the bladder and was separated without revealing any communication. Under this the tip of the appendix was found adherent to the bladder at about the peritoneal reflexion over the uterus in the middle line. The appendix was about 7 centimetres long. A cuff containing peritoneum and muscular coat was turned back from either end and the middle part was cut away. The stumps were disinfected, the cuffs were ligatured over the stumps, and the abdomen was closed. Recovery was uneventful. It is remarkable that there was no history of a definite attack of appendicitis. Rupture of an appendicular abscess into the bladder is common, but only two cases appear to have been recorded in which this gave rise to a permanent fistula. Dr. W. W. Keen has reported a case in which "the appendix became soldered to the bladder, producing a urinary-fæcal fistula" This patient was a man who, at the age of 24 years, passed in the urine seeds, pus, and intestinal débris. The fistula existed for some years before operation.

TYPEWRITING AND METABOLISM.

THE *Journal of Biological Chemistry* for June contains an interesting study of the metabolism of man during the work of typewriting, by Mr. Thorne M. Carpenter and Mr. Francis G. Benedict. In the past 30 years there has been a remarkable development in the use of mechanical machines for writing, and the typewriter of the present day has very largely displaced handwriting, particularly in commercial correspondence. The major movements involved in typewriting are much greater than those involved in writing with a pen, and this suggested that there might be a corresponding increase of metabolism as a result of using a typewriter as compared with handwriting, even on the basis of the elimination of energy per 100 words. The typewriter shows a marked increase in speed over handwriting and entails an enormous amount of work, which appears to be done without excessive fatigue by women who are not muscularly as well developed as is the ordinary man. It is important to have some idea of the amount of energy required for writing with such appliances, and the problem is of great interest and serves admirably to indicate the possibilities of accurate scientific instruments for studying questions having a practical everyday value. The general plan of experiment was as follows. The subject entered a special chamber, constituting a respiration calorimeter, usually after a meal, and sat quietly in an arm-chair, with a table before him, reading for an hour or so until the calorimeter was in perfect equilibrium. At this time analyses were made of the residual air, and the heat measurements were begun After the resting period the subject used a typewriter, a record being made of the number of words written and the time occupied. Owing to marked differences in the temperaments of the individuals and in the degree of skill in typewriting, a comparison is at best somewhat speculative, but the data obtained afford a general idea of the work involved in typewriting. It would appear that the work of writing from 1500 to 1600 words per hour on the typewriter results in an increase over the resting metabolism of 10 to 14 grammes of carbon dioxide, 10 to 13 grammes of oxygen, and 20 to 30 calories of heat per hour. Of these factors of metabolism it is highly probable that the truest factor is presented by the total energy exchange as directly measured. From the studies of gaseous exchange made by Zuntz and his associates it has been computed that there is an hourly energy expenditure of about 160 calories over and above the resting maintenance requirement of a man weighing 70 kilogrammes walking along a level road at a rate of 2·7 miles per hour. It is clear, therefore, that the work of typewriting calls for very much less transformation of energy than does that of ordinary walking, but Mr. Roosevelt has scientific sanction for his inclusion of typewriting amongst the strenuous activities of life. We have agreed with the ex-President in this estimate, since we discovered that a quarter of a pound weight was necessary to depress one key of a commercial typewriter, which may be considered a standard machine. From the point of view of office life, the exercise appears to us to be a distinct advantage to the operator.

THE TUBERCULOSIS EXHIBITION AT THE WHITE CITY.

THE Tuberculosis Exhibition, which was inaugurated in the early summer at the Whitechapel Art Gallery by the National Association for the Prevention of Consumption and Other Forms of Tuberculosis with such success that 70,000 people visited it in its East-end quarters, has now been moved to Shepherd's Bush, where it forms one of the features of the White City. On August 6th Lord Balfour declared the Exhibition open in the Machinery Hall in the presence of Sir William S. Church, Sir Hermann Weber, Dr. C. Theodore Williams, Dr. Edward Squire, Mr. H. Hammond Smith, and others prominently associated with the national prevention of tuberculosis. The exhibits are in all respects similar to those shown at Whitechapel, which we have described. A fresh inspection has confirmed our opinion of their educational value, and we were especially impressed with the excellence and completeness of the section devoted to the Edinburgh anti-tuberculosis scheme, with its large scale reproduction of a ward at the Victoria Hospital for Consumption at Craigleith, and the many striking diagrams and models each with its salutary lesson. The Paddington Tuberculosis Dispensary also makes a good show, and the many large photographic views of human sleeping-dens, veritable nests of tuberculosis, serve to draw prominent attention to the urgency of the housing problem in our large cities as a prime necessity of the national health. There is, however, one defect in connexion with the present exhibition which we should like to see remedied. We visited it after sunset and found it difficult to see the various objects and charts properly, as they are only lighted by the arc-lamps hanging from the roof of the large Machinery Hall which are quite inadequate for the purpose. This is a great pity, especially as the many trading stalls situated beyond the Exhibition in the same hall are all brightly lit with their own electric light. At the time of our visit these were attracting far more attention than the Tuberculosis Exhibition through which people passed to reach them. In fact, by 9 o'clock, many of its models were being covered up for the night, and the lessons to be derived from entering the model "ideal" and the "real" living rooms of the poor consumptive were quite lost, because an equal darkness pervaded both, even the wide open windows of the latter not admitting enough light from without to show its features properly. We think, too, that prominent notices might be put up outside the Machinery Hall and in some prominent places in the grounds calling attention to the Tuberculosis Exhibition, the existence of which does not seem to be generally known amongst the attendants. This is the more to be regretted as a large number of holiday-makers in London may be expected to visit Shepherd's Bush during this month, and the Tuberculosis Exhibition must be made as attractive as other shows in the grounds if it is to have a proper educational effect. We hope that the appeal for funds to put the Tuberculosis Exhibition on a permanent travelling basis which is now being circulated by the National Association for the Prevention of Tuberculosis may meet with sufficient response, and may add that any who wish to help this beneficent movement should communicate with Dr. J. J. Perkins, Secretary of the Association, at 20, Hanover-square, London, W.

THE PATHOLOGY OF LANGUAGE.

"THE chemists have called 'caloric' what they ought to have called 'calorific.' The Lavoisierian nomenclature, whatever it merits in other respects, is a system of philological monstrosities in which it is fortunate when the analogies of language are only violated and not reversed." So said Sir William Hamilton, and justly. To take an immediate instance: Lavoisier's coinage, "oxygen," can, in philological strictness, mean only that which is "begotten of acid," not that which begets it (as he meant to convey)—Διογενής, for instance, on the analogy of which it is formed, meaning only "Jove-born," not "Jove-bearing." And so on, *ad infinitum*. Sir William Hamilton's compatriot, John Stuart Mill, after endorsing his dictum that "to the Schoolmen the vulgar languages are indebted for whatever precision and analytic subtlety they possess," follows it up with a trenchant onslaught on the harm wrought to language and, *pro tanto*, to exact thinking, by the unscholarly use of words in spoken and written discourse. It will hardly be believed, he says in effect, what circumlocutions the philosophic or scientific thinker is driven to in order to avoid a word which, as originally coined, would have served his purpose perfectly but which has, by unintelligent use, been so deflected from its true meaning that some substitute for it has to be found, at whatever cost. So many men, he adds (writing in 1856), "without even the semblance of an education," are now professional authors, that the language is becoming steadily spoiled for those who can employ it legitimately. And he gives a long list of examples which may be found in the fourth edition of his "Logic." Even in a book which, within the last 18 months, has had middle-class readers by the million, written as it is by a "professional author" who comes under Mill's category, we read of the protagonist's "lying prone on his back"—a *bêtise* which a first year's student in anatomy who had been taught the difference between "pronation" and "supination" could not possibly have perpetrated. To what uses language can be degraded is apparent to anyone whose daily walk may be between hoardings covered with advertisements the pretentious terminology of which would make Milton, as well as Quintilian, "stare and gasp." 60 years ago D'Israeli, in his "Tancred," made delicious fun of the worn-out phraseology then in vogue, much of which survives, with tenacious vitality, after wounds like those of Hamilton and Mill and D'Israeli himself, that should have been mortal! What Mr. George Wyndham in his brilliant preface to the reprint of that "well of English undefiled," North's "Plutarch," calls the "charnel house of decayed metaphor" (meaning the fetid common-places of conventional diction written and spoken), is still drawn upon by the platform declaimer and the prolific novelist to an extent that makes one despair of the future of our language. But such phraseology seems endowed with a charmed life and we shall still be reading of a controversialist "taking up the cudgels" [who takes up "cudgels?" and why more than one?] or "embarking on the next feature on which this question hinges," till we are well-nigh driven to envy the blind or the deaf-mute his privations, or the unlettered his ignorance, or to surmise that Milton, could he be called from the tomb, would almost repent of his having vindicated the "art of printing."

GERMAN TOURS FOR MEDICAL MEN.

THE ninth German tour for medical men will commence on Sept. 3rd and will continue till the 20th, the work of organisation being conducted by the German Central Committee for Medical Tours (*Zentralkomitee fur arztliche Studienreisen*). The permanent address of the general secretary of this committee is Dr. A. Oliven, Berlin N.W. 6, Luisenplatz 2-4 (Kaiserin Friedrich-Haus für das ärztliche Fortbildungswesen), but in connexion with the forthcoming tour he will from August 28th to Sept. 3rd have an office in the Grand Hotel Hungaria in Budapest, to which all communications should be forwarded. The preliminary business will commence on the forenoon of Sept. 2nd in the lecture-room of the Physical Institute in Budapest, when Dr. Sig. von Gerlóczy will deliver an address on the local warm springs, after which visits will be paid to the warm baths of the city and to the Saxlehner bitter water springs, under the guidance of Professor A. von Bokay. The party will leave Budapest by train at 7 A.M. on Sept. 3rd, and will spend that and the three following days in various places in Hungary and Austria, the towns visited on those days being successively Pystian, Trenczin-Teplitz, Siofok, Balaton-Fuered, and Abbazia. In all these towns visits will be paid to places of medical interest, such as bathing establishments, sanatoriums, hospitals, &c.; receptions will be held, and addresses will be delivered by local notabilities. Leaving Abbazia on Sept. 7th at 7.30 A.M. the party will proceed by steamer to Venice, where the afternoon and the whole of the next day wil be spent in sightseeing and entertainments. On the 9th the party will arrive at Genoa at 8 A.M. and will leave at 4 P.M. by the North German Lloyd steamer *Prinz Ludwig* for Algiers, which will be reached on the 11th at 8 A.M. The five days from the 12th to the 16th inclusive will be spent mostly at sea, when an address will be delivered daily, three of the subjects discussed being cancer, neurasthenia, and the hygiene of health resorts. The steamer is timed to call at Gibraltar on the 12th at 5 P.M. and at Southampton on the 16th at 1 P.M., and to arrive at Antwerp on the 17th at 11 A.M. The last of the formal meetings will be held on board the steamer on the 19th during the passage from Antwerp to Hamburg, where the party will disperse.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies stated that 6 cases of plague, with 5 deaths, were reported during the week ending August 5th, and the Governor of Hong-Kong reported 3 cases of plague with 3 deaths during the week ending August 8th

Mr. Edward Douglas Madge, M.R.C.S. Eng., L.R.C.P. Lond., has received the King's Royal licence and authority to accept and wear the Cross of Officer of the Star of Roumania, conferred upon him by His Majesty the King of Roumania in recognition of valuable service rendered by him.

WE are requested to call attention to the change of address of the London Post-Graduate Association. All communications should now be sent to 20, Hanover-square, W.

SANITATION IN WEST AFRICA.[1]

EARLY in January, 1908, plague broke out at Accra in the Colony of the Gold Coast, and as considerable alarm was experienced lest the disease should spread to other places in West Africa Professor W. J. R. Simpson was asked by the Secretary of State for the Colonies to proceed to Accra to take over the control of the arrangements for dealing with the threatened epidemic. He accordingly left England for the Gold Coast on Jan. 18th, accompanied by Dr. J. A. Haran of the East African Medical Service as his assistant. He was also instructed to visit other towns and districts in the West African colonies of Sierra Leone, the Gold Coast, and Southern Nigeria *to inquire into their sanitary condition*. He likewise received instructions to confer with the local authorities respecting their quarantine laws in order that

with modern practice.

West Africa Professor

rtunities he found for inquiring into the effectiveness of the existing organisation and equipment of the medical service in these colonies from the public health point of view. This report, which is now issued as a Parliamentary paper by His Majesty's Stationery Office, contains 90 printed pages of folio and is illustrated by 80 photographs with 13 maps and plans.

In the present report only a summary of the investigations into the plague epidemic is given, as the detailed report on the outbreak is being published separately by the Government of the Gold Coast. From this summary we find that from January to October, 1908, the notified plague cases in the Gold Coast colony numbered 344, of which 300 proved fatal, yielding a case mortality of 86·6 per cent. The epidemic which commenced at Accra was carried, by panic-stricken natives fleeing for refuge, to other places in the colony, among which may be mentioned Nianyano (a village of less than 1000 inhabitants, where 64 persons died from the malady), Annamaboe, and Brewa. The last-named village, thoug

listant from

Cape

conveyed,

but o

at Accra, where 157 deaths were recorded, was mainly bubonic in type and was associated with a plague epizootic among rats. The prevalence in the outlying villages was of the pneumonic kind and was accompanied by no observed infection or mortality in rats. The actual source of the plague and how it was brought to Accra are not given in the published summary. Prior to Professor Simpson's arrival a public health committee had been formed at Accra and certain measures had been adopted for cleansing the town, isolating the sick, segregating the contacts, demolishing infected houses, and for destroying rats. Later, preventive inoculation by Haffkine's method was carried out and was welcomed by the people, *no fewer than* 35,000 persons submitting to the operation without a single untoward result. A laboratory was established for the purpose of aiding the diagnosis of plague and for the preparation of Danysz's rat virus. A land cordon was formed round Accra to prevent the escape of infected persons into the surrounding villages. Persons whose business required them to leave the town had to submit to prophylactic inoculation and were supplied with passports which bore the thumb marks of the possessor, who also carried a certificate that he had been inoculated signed by a Government medical officer. Measures, too, were taken to prevent infection being carried by ships to other ports on the Gold Coast or neighbouring colonies. These measures appear to have been entirely successful in getting rid of the disease. As the colonies of Sierra Leone, the Gold Coast, and Southern Nigeria had different quarantine laws some confusion at first arose in dealing with vessels arriving at the

led Professor Simpson

and provision for disinfection they could abolish quarantine along with its vexatious restrictions upon shipping and commerce. But it is admitted that native deck passengers would still require special treatment. Uniformity of port regulations, it is pointed out, would be of great advantage to all the colonies concerned. Much has already been done to act upon the advice given by Professor Simpson, but more remains to be accomplished before the port equipment of these colonies is complete.

---

[1] Report to the Colonial Office by Professor W. J. R. Simpson on Sanitary Matters in Various West African Colonies and on an Outbreak of Plague in the Gold Coast. Printed for His Majesty's Stationery Office by Darling and Son, London. Price 9d.

As regards the sanitary condition of the chief towns and trading centres in the three colonies of Sierra Leone, Gold Coast, and Southern Nigeria, Professor Simpson visited and inspected a number of places and reported upon their sanitary circumstances and administration. He prefaces his remarks by mentioning that owing to the absence of any complete system of registration of deaths he is unable to give any statistical evidence as to the effect of insanitary conditions on the health of Europeans or natives. Nor could he obtain trustworthy data for compiling a sick-rate. But he gives us to understand that neither sickness nor mortality among Europeans is anything like so great as it was in the past. He draws attention to the importance of good housing upon the health of European residents; special attention he finds has been paid in some places to improving the means for storage and protection of the water-supplies used by European officials, but public health measures have still to be taken for the benefit of the general population. His report gives details of the conditions existing in Freetown, Accra, and Lagos, as well as in some other trade centres. He mentions in general terms the insanitary conditions of the places he inspected. In the Gold Coast Colony alone he visited over 50 places and the chief defects common to nearly all of them were the lack of protection of wells, absence of good surface drainage and consequent malarial conditions during rains, unnecessary crowding together of huts upon area notwithstanding the abundance of unoccupied land, unhealthy placing of huts with obstruction of light and ventilation, and the existence of rank vegetation close to dwellings. Most of these conditions, it appears, can be easily remedied or prevented altogether; but there is no special health or sanitary department belonging to each colony interested in, and responsible for, this work. The climate of West Africa, particularly in the interior and away from the coast, is no worse and no more depressing than some other tropical regions; but the prevailing conditions are usually so primitive and so insanitary that there is considerable risk of injury to the health of Europeans who have to reside among them. Professor Simpson thinks that at present sanitary measures need to be concentrated especially on the towns, villages, rest-houses, and encampments. The large marshes away from the villages and towns have little to do with the unhealthiness of the coast. Sanitation need not involve the reclamation and drainage of the West African marshes unless these are close to inhabited places. He gives some rules for laying out new villages on sanitary lines. All this leads up to the need of creating a special health organisation to improve the present insanitary conditions, and he gives some detailed suggestions for constituting a new health authority. We understand that Professor Simpson, when giving evidence recently before the Departmental Committee which the Secretary of State for the Colonies appointed to inquire into the West African Medical Staff, laid before that body his scheme for establishing a special health department in each colony, making it a branch of the West African Medical Staff separate in its functions and its officers not transferable to other medical duties. Those who are interested in sanitation in tropical countries will find much information in Professor Simpson's detailed account of the sanitary condition of Freetown, Accra, Sekondi (the "gateway of the interior"), Cape Coast, Lagos, Forcados, Calabar, and other places described in the latter portion of this interesting report. We are quite in agreement with the contention that if these West African towns and villages are to be rendered healthy their supervision must be undertaken by skilled and specially trained responsible sanitary officials, under whose advice schemes for water-supply, drainage, excrement and refuse disposal, housing and town planning will be carried out, as well as measures for preventing the spread of epidemic and endemic diseases, and the keeping of a strict watch over the actual state of streets and dwellings. Such officials, too, would see to the enforcement of by-laws and regulations framed for the improvement of the public health and for the protection of the native populations.

METROPOLITAN HOSPITAL SUNDAY FUND.

At the Mansion House on July 28th the Lord Mayor presided at a meeting of the Council of the Metropolitan Hospital Sunday Fund, the object of which was to receive the report of the Committee of Distribution and to order the payment of awards to hospitals, dispensaries, and nursing associations.

The report of the Committee of Distribution stated that the executors of the late Mr. George Herring would pay to the treasurer of the Fund £24,000, being the balance of income available from the estate, which, with £1352 received in dividends, &c., upon securities transferred to the Fund, made the total income from this source to date £25,352. The committee recommended that this sum should be added to the collections, making the total of the Fund to date £67,951, in which is included £2000, the balance of the legacy of £10,000 under the will of the late Mr. Herbert Lloyd; £900, being the legacy, less duty, of the late Mr. Edwin Gayford; and £500 on account of the legacy of the late Mr. C. E. Layton. This year 258 institutions had applied for grants from the Fund, being one less than in 1908. Two institutions were considered ineligible. The committee recommended the distribution of £67,212 to 164 hospitals and institutions, 59 dispensaries, and 30 nursing associations. 5 per cent. of the total sum available for distribution was appropriated to the purchase of surgical appliances during the ensuing year, and 2½ per cent. for district nursing associations.

Sir William Church, in moving that the report be received, said that this was the first time that the Battersea General Hospital—usually known as the Antivivisection Hospital—had been included in the list of institutions receiving a grant. He explained that the reason why this institution had not previously appeared on the list was that the hospital was not founded and maintained with the sole object of relieving the sick and suffering poor, but was also founded and maintained for keeping prominently before the public the work of antivivisectionists The members of its medical staff were narrowed down to medical men who, rightly or wrongly, did not believe in vivisection, and the distribution committee had felt that in these circumstances they were not justified in granting an award to an institution thus limited in its scope and work. This year the committee had been approached by various members of the council, including some of the clerical members, with regard to the Battersea Hospital, and the committee, while still disapproving of the way in which the hospital was carried on, desired to bring the matter before the Council. If the Council determined that a grant should be made the committee would amend the grant recommended and advise a grant on the full basis, which would double the proposed amount and make it £97 10*s*.

Lord Leith of Fyvie seconded the proposition.

Mr. Thomas Bryant moved an amendment to the effect that the grant should be omitted. He said that the hospital cast a great slur upon the profession generally, and he knew that cases had gone from the Antivivisection Hospital to the Bolingbroke Hospital which had been badly treated.

There being no seconder the amendment was not put to the meeting.

Sir Henry Burdett hoped that the authorities of the hospital in question would purge themselves of their pretence as to the special advantages claimed from the antivivisectionist's point of view. He hoped that now they had obtained the grant they would treat disease in a straightforward and honest manner.

The report having been adopted and the awards ordered to be paid, a vote of thanks was accorded to newspapers which had pleaded the cause of the Fund and the meeting terminated with the usual courtesies to the chairman.

The following is a list of the awards recommended:—

General Hospitals.

MEDICINE AND THE LAW.

A Certificate of the Cause of Death followed by an Inquest.

IN a letter published in THE LANCET of July 31st, p. 321, referring to an annotation in our issue of July 24th, p. 243, Dr. E. J. Toye quoted from Section 20 of the Births and Deaths Registration Act, 1874 (37 and 38 Vict., cap. 88), the words, "In the case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and *give to some person required by this Act to give information* concerning the death a certificate stating to the best of his knowledge and belief the cause of death." From this Dr. Toye argues that a medical man has no discretionary power to withhold a certificate which, in the words of the annotation referred to, "cannot conscientiously be granted." The word "shall," no doubt, is mandatory, but the medical man has to consider the facts of his case and to apply the law to them. He has to consider whether he did attend the deceased during his last illness, and in the case commented upon in the annotation the coroner's jury, and the coroner who presided, appear to have had doubts upon this point, although they did not employ the words of the section. At all events, if the certificate had been refused and adverse comment had been made, that would have been one of the answers open to the medical man. Again, he may not have such "knowledge and belief" as will justify him in assigning a cause. "The best of a medical man's knowledge and belief" is an expression which does not imply absolute certainty, but equally it does not include mere suspicion or an opinion for the formation and confirming of which his opportunity has been insufficient. As to that sufficiency he is the best judge. It is not quite easy to see what Dr. Toye means when he writes, "The duty of the medical man would simply be that of signing a certificate in all cases of death, whether due to natural or violent causes." The question must still arise whether the medical man attended the deceased during his last illness within the meaning of the section. Dr. Toye's quotation is from the Subsection 2 of Section 20. Subsection 3 is as follows: "Where an inquest is held on the body of any deceased person a medical certificate of the cause of death need not be given to the registrar, but the certificate of the finding of the jury furnished by the coroner shall be sufficient." The section ends as follows: "If any person to whom a medical certificate is given by a registered medical practitioner in pursuance of this section fails to deliver that certificate to the registrar he shall be liable to a penalty not exceeding forty shillings," so that apparently Subsection 3 is intended to apply so as to exempt the medical man from giving a certificate in the class of case referred to, and not to excuse the person to whom it has once been given from passing it on. In conclusion, it may be pointed out that the withholding of a certificate of the cause of death by a medical man in cases where he has attended during a last illness is usually due to some element of doubt, the elucidation of which is outside his functions and beyond his powers.

Workmen's Compensation: Hughes v. Glover, Clayton, and Co.

The widening of the meaning of the word "accident" in order that compensation may be granted by employers to the dependents of deceased workmen has been a noteworthy feature in recent decisions under the Workmen's Compensation Act, 1906. In the latest case, Hughes *v.* Glover, Clayton, and Co., decided by the Court of Appeal, the workman, who was employed by a firm of shipbuilders, was engaged in tightening a nut with a spanner, when a companion saw his foot slip forward and then saw him fall on his back. He was found to be dead, and post-mortem examination showed that a very large aneurysm of the aorta had ruptured, the medical evidence being to the effect that in the condition in which it had been this result might have taken place from very slight exertion or might even have occurred during sleep. It was not proved that the slip of the foot mentioned was in any way responsible for the death, and the finding of the county court judge and the judgment of the Court of Appeal were based upon the assumption that, in fact, the man had suffered from aneurysm and that the exertion of using the spanner in the ordinary course of his work had brought about the death which might have ensued at any time upon any other not extraordinary cause. The county court judge held, however, that on the authority of cases already decided the death under consideration was due to an accident and the Court of Appeal upheld this decision. The case upon which stress was laid in the judgment delivered by the Master of the Rolls was that in which a workman in a weak state of health was allowed to try to work his way home in the stokehold of an Atlantic liner, where he succumbed to heat stroke and died while performing the ordinary duties of a stoker. The Master of the Rolls cited the following passage from the judgment then delivered by Lord Loreburn, who said: "To my mind the weakness of the deceased which predisposed him to this form of attack is immaterial. The fact that a man who has died from a heat stroke was by physical debility more likely than others so to suffer can have nothing to do with the question whether what befel him is to be regarded as an accident or not. ...... It was an unlooked-for mishap in course of his employment. In common language, it was a case of accidental death." Another case cited was that of Stewart *v.* Wilson's and Clyde Coal Company (5F. 120) in which Lord Maclaren said: "If a workman in the reasonable performance of his duties sustains a physiological injury as the result of the work he is engaged in, this is an accidental injury *in the sense* of the statute." The Master of the Rolls concluded his judgment by saying: "In the present case the workman, in the reasonable and ordinary discharge of his duties, had sustained an injury, a rupture of the aorta. That injury was the result of the work in which he was engaged and the appeal must therefore be dismissed with costs." Possibly this most recent decision, like others, will not be considered to be fully established until it has been submitted to the House of Lords, but the Court of Appeal has apparently followed the precedents laid down in cases already decided by that tribunal. It may be questioned whether Lord Loreburn's opinion was that the case upon which he was delivering judgment was "in common language a case of accidental death." It will seem to many a straining of "common language" to make "accident" include the natural result of any kind of work deliberately undertaken by a person physically unfit to engage in it. Such, however, is the legal interpretation of the word as used in an Act of Parliament which imposes a liability upon practically all employers, and the cases referred to point to the desirable precaution on the part of employers of making all those in their service submit to physical examination before engagement and periodically afterwards. Workmen whose soundness is in any degree open to question are likely to find themselves in the ranks of the unemployed, and the imposing of medical examination upon workmen may bring some employers into collision with trades unions, but these are questions which we need not discuss here. The medical man, who presumably is acquainted to some extent with the physical weaknesses of his coachman, chauffeur, gardener, or other servant of either sex, will do well to note the liability imposed upon him by the law, and will remember that he cannot contract himself out of it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7472 births and 3311 deaths were registered during the week ending August 7th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 12·6 to 10·6, further declined last week to 10·5, a lower rate than in any previous week of this year. During the first five weeks of the current quarter the annual death-rate in these towns averaged only 11·0 per 1000, and in London during the same period it did not exceed 10·6. The lowest recorded annual death-rates last week in the 76 towns were 3·8 in East Ham, 5·3 in Walthamstow, 5·7 in King's Norton, and 5·8 in Bourne- [illegible] he rates in the other towns [illegible] in Bootle, 15·1 in Liver- [illegible] and 18·0 in Newport (Mon.). In London the recorded death-rate last week did not exceed 10·1 per 1000. The 3311 deaths from all causes in the 76 towns last week showed a decline of 86 from the low number returned in the previous week, and included 336 which were referred to the principal epidemic diseases, against 313 and 315 in the two preceding weeks; of these, 127 resulted from diarrhœa, 83 from measles, 52 from whooping-cough, 34 from diphtheria, 28 from scarlet fever, and 12 from "fever" (principally enteric), but not one from small-pox. The 336 deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·0 in each of the three preceding weeks. No death from any of these epidemic diseases was registered last week in Croydon, Tottenham, Stockport, Hornsey, Rochdale, York, or in 11 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·7 in Rhondda, 2·9 in Wigan, 3·0 in Middlesbrough, 4·7 in Newport (Mon.), and 5·2 in West Bromwich. The deaths attributed to diarrhœa in the 76 towns, which had increased in the five preceding weeks from 59 to 113, further rose to 127 in the week under notice, and was relatively most fatal in Swansea, Wigan, and Nottingham. The fatal cases of measles, which had steadily declined in the four preceding weeks from 138 to 80, were 83 last week, and caused annual death-rates equal to 1·3 in Coventry and in Salford, 1·5 in Bootle, 4·0 in Newport (Mon.), and 4·4 in West Bromwich. The 52 deaths from whooping-cough exceeded by four the number in the previous week, causing annual rates equal to 1·0 in Middlesbrough and 1·2 in Wigan. The 34 fatal cases of diphtheria showed [illegible]

[illegible] patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospitals, which had been 2737, 2731, and 2667 on the three preceding Saturdays, had further declined to 2564 at the end of last week; 280 new cases of this disease were admitted to these hospitals during last week, against 415, 367, and 296 in the three preceding weeks. The registered deaths in London last week referred to pneumonia and other diseases of the respiratory organs, which had been 132 and 106 in the two previous weeks, rose again last week to 120, but were two below the corrected average number in the corresponding week of the five years 1904–08. Only one death in London last week was directly referred to influenza. The causes of 31, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered last week were again duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Salford, Portsmouth, and in 53 smaller towns; the 31 uncertified causes of death in the 76 towns included nine in Liverpool, six in Birmingham, and two both in St. Helens and in Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 874 births and 429 deaths were registered during the week ending August 7th. The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 15·5 to 11·8, was last week equal to 11·9. During the first five weeks of the current quarter the death-rate in these Scotch towns averaged 12·3 per 1000; in the 76 large English towns the mean death-rate during the same period did not exceed 11·0. The death-rate last week in these Scotch towns ranged from 9·8 and 9·9 in Aberdeen and Perth, to 13·2 in Dundee and 14·4 in Greenock. The 429 deaths in the eight towns last week exceeded by six the low number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 45 and 39 in the two preceding weeks. These 50 deaths were equal to an annual rate of 1·4 per 1000, against 1·3 and 1·1 in the two preceding weeks; the rate last week from the same epidemic diseases in the 76 large English towns was equal to 1·1 per 1000. Of the 50 deaths last week in the eight Scotch towns from these epidemic diseases, 20 resulted from diarrhœa, 14 from whooping-cough, six from measles, four from "fever," and three both from scarlet fever and diphtheria, but not one from small-pox. The deaths attributed to diarrhœa, which had been 14 and 13 in the two preceding weeks, rose last week to 20, of which seven occurred in Glasgow, four in Edinburgh and in Dundee, and two each in Paisley and Greenock. The 14 fatal cases of whooping-cough were within one of the number in the previous week, and included five both in Glasgow and in Edinburgh. Of the six deaths from measles, against 14 and three in the two preceding weeks, three were returned in Glasgow and two in Aberdeen. The four deaths referred to "fever" slightly exceeded the numbers in recent weeks, three being certified as enteric, and one (in Aberdeen) as cerebro-spinal meningitis. Two of the three deaths, both of scarlet fever and diphtheria, were returned in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 76, 49, and 43 in the three preceding weeks, rose again to 51 in the week under notice, but were three below the number returned in the corresponding week of last year. The deaths in the eight towns last week included 17 which were referred to different forms of violence, of which 10 occurred in Glasgow. The causes of 11, or 2·6 per cent., of the deaths in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 14·4 and 17·4 per 1000 in the two preceding weeks, declined again to 15·2 in the week ending August 7th. During the first five weeks of the current quarter the death-rate in the city averaged 15·9 per 1000, whereas the mean rate during the same period did not exceed 10·6 in London and 12·8 in Edinburgh. The deaths of Dublin residents from all causes last week showed a decline of 17 from the number in the previous week, and included 12 which were referred to the principal epidemic diseases, against nine and 15 in the two preceding weeks. These 12 deaths were equal to an annual rate of 1·6 per 1000, the death-rate from the same epidemic diseases last week being equal to 0·9 in London and to 1·9 in Edinburgh. Of the 12 deaths from these epidemic diseases in Dublin last week, five resulted from diarrhœa, four from whooping-cough, and one each from measles, diphtheria, and "fever," but not one either from scarlet fever or small-pox. The fatal cases both of diarrhœa and whooping-cough corresponded with the numbers in the previous week. The 116 deaths at all ages included 25 of infants under one year of age, and 29 of persons aged upwards of 60 years. Five inquest cases and five deaths from violence were registered during the week; and 40, or 34·5 per cent., of the deaths occurred in public institutions. The causes of four, or 3·4 per cent, of the deaths registered in the city last week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all but one of the 933 deaths registered were duly certified, and in Edinburgh all the causes of death were certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Staff-Surgeon Edward Francis Power has been placed on the retired list (dated July 28th, 1909).

The following appointments are notified:—Fleet-Surgeons: F. J. A. Dalton to the *New Zealand*, on recommissioning; and G. Ley to the *Juno*, on recommissioning. Staff-Surgeons: W. G. Westcott to the *Excellent*, additional, for the *Revenge;* R. H. Mornemont to the *Eclipse*, on recommissioning; L. Lindop to the *New Zealand;* C. R. Sheward to the *Majestic*, on recommissioning; and J. Whelan to the *Adventure*, on recommissioning. Surgeon: S. N. Scott to be surgeon and agent for duty with civilian workmen at Turnchapel and Oreston injured while on duty.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains (dated July 30th, 1909):—Charles M. Drew, Archibald A. Sutcliff, Arthur G. Cummins, Hugh E. Gotelee, Archibald S. Littlejohns, William R. Galwey, Frank A. McCammon, George De la Cour, William Egan, Robert G. H. Tate, Alexander Dawson, Frank Forrest, Augustus S. Williams, Victor C. Honeybourne, Clive T. Edmunds, Valentine G. Johnson, Charles R. M. Morris, Richard E. U. Newman, Ernest W. M. Paine, Frederick D. G. Howell, William H. Gillatt, Patrick Sampson, Marcus G. Dill, John B. G. Mulligan, Edward M. O'Neill, Georgie B. Edwards, John W. L. Scott, William C. Smales, Arthur H. Bond, Thomas C. C. Leslie, Donald De C. O'Grady, Lawrence G. Gibson, Philip S. Stewart, and Timothy W. O. Sexton. The undermentioned Lieutenants are confirmed in that rank: Spencer G. Walker, James A. Clark, Harold H. Leeson, William G. Wright, Albert T. J. McCreery, Harry S. Ranken, John A. Manifold, Samuel S. Dykes, Robert C. Priest, Percy S. Tomlinson, Alexander D. Stirling, George P. Taylor, Robert C. Paris, Alfred W. Bevis, Ernest C. Lambkin, Oswald W. McSheehy, Maurice J. Williamson, Charles L. Franklin, Michael White, James J. D. Roche, James R. Hill, Herbert F. Joynt, Alexander S. M. Winder, James R. Yourell, Philip G. M. Elvery, John Beckton, and William B. Rennie.

INDIAN MEDICAL SERVICE.

Major F. D. Browne, has been appointed to the substantive medical charge of the 112th Infantry at Kohat. Captain A. S. M. Peebles has been appointed to the substantive medical charge of the 18th Lancers, vice Captain R. F. Baird. Lieutenant N. J. Simpson has been appointed to officiate in medical charge of the 2nd-9th Gurkha Rifles. Lieutenant J. B. Lapsley has been appointed to the 3rd Brahmans, and also to hold medical charge of the Cantonment Hospital, Agra.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st South Western Mounted Brigade Field Ambulance: Major George R. Swinhoe resigns his commission (dated May 13th, 1909).

For attachment to Units other than Medical Units.—Arthur Herbert Norris to be Lieutenant (dated June 22nd, 1909).

THE TERRITORIAL CAMPS.

The *Times* military correspondent, referring to the field operations in the New Forest, says that the physique of the men is excellent. The Salisbury correspondent, in referring to the death of a trooper belonging to the City of London Yeomanry, states that the death was quite independent of camp life. "The sanitation of the camps is perfect, and the cooking of the food could not be better in a restaurant working upon a similar scale." He, however, points out that "an aggravation of ...... heat trouble in many instances was the lack of drinking water. Many of the men had emptied their water-bottles long before the morning's operations were over, and no water was to be found at any distance from the camp." The selection of water-supplies for a camp was discussed in the second instalment of the articles on the Territorial Medical Service which appeared in the last issue of THE LANCET, p. 416, and stress was laid upon "quantity."

THE ROYAL VICTORIAN ORDER.

In connexion with the recent visit of the Emperor and Empress of Russia to this country the King has appointed Staff-Surgeon John Smirnoff and Staff-Surgeon Serge Lentovsky, honorary surgeons to His Imperial Majesty, to be Honorary Members of the Fourth Class of the Royal Victorian Order.

THE RED CROSS SOCIETY.

Sir Frederick Treves, referring at a meeting of the British Red Cross Society at Horsham on August 10th to the memorandum which the War Office was about to issue calling upon the Red Cross Society to take the place it ought to take in connexion with the defence of the country, said that the document would be published in the course of two or three days.

Correspondence.

"Audi alteram partem."

THE NATURE OF ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—I trust you will allow me a little space, as I could not be at the Belfast meeting, to express my dissent from the views advocated by Sir Clifford Allbutt referred to in your abstract of his paper at pp. 336-7 of your last number in July.

Sir Clifford Allbutt's positive assertion I do not dispute. I quite agree that stretching of the supra-sigmoid portion of the diseased aorta will account for anginal symptoms in a certain number of cases—which are recognisable by fairly definite symptoms,—but whilst Sir Clifford Allbutt has earned the gratitude of clinicians by having so carefully pointed out this mechanism, he must not expect them to accept without challenge his view that aortic stretching is the only mechanism of anginal suffering. The mechanism of angina consists of one or other of at least three or four combinations, and the modes of death, too, are several. The terms angina major and angina minor adopted by Sir Clifford Allbutt imply degrees of the same thing, and as he seems to regard angina as a disease by itself and not a symptom or a syndrome, the terms appear to me to be only justifiable on the view that it also has only one pathology. In this view I cannot acquiesce.

Clinically, as one meets with cases, I would emphatically maintain that the radiating reflection of the pains to one or both arms, to the throat and shoulder. is by no means peculiar to cases of the graver kind of angina, although it may be more frequent in them. I have seen the most acute anginal suffering, with central agony and reflected pains, in [illegible] in which there is [illegible] and in which time [illegible]

[illegible] I do not regard vaso-motor spasm [illegible] of angina. But what is under- [illegible] cannot be dismissed in the light-hearted manner of the professor, for the vaso-motor phenomena are in many cases of the very essence of the picture. In certain cases of organic heart disease with anginal attacks, any of which may be fatal, the acute anginal attack is started and maintained by the vaso-motor spasm and is relieved by the relief of that spasm. I have recorded in Sir Cliffo [illegible] a case of the mos [illegible] regurgitant disease I [illegible] and th [illegible] I have witnessed other [illegible] but of textural heart [illegible] the attack was the same, and I have seen others again—which alone I would regard as cases of pseudo-angina, although I do not like the term—in which there is angina of vaso-motor origin, which may be even severe, but in which the heart—the criterion in prognosis—is sound.

The "pretty fancy" of intermittent claudication, to which Sir Clifford Allbutt playfully alludes, seems to me to be based [illegible] and analogy by Burns, Brodie, [illegible] been supported by some recent [illegible] by Dr. Parkes Weber on ana [illegible] of excessive smokers. But I have already made this letter too long, and for a full explanation of the views which, from reading and experience, seem to me to be most tenable respecting this grave and interesting malady, I must refer the reader to my revised article in the coming volume of Sir Clifford Allbutt's "Cyclopædia of Medicine."

I am, Sir, yours faithfully,

London, August 9th, 1909. R. DOUGLAS POWELL.

AN OPERATION FOR THE TOTAL EXCISION OF TONSILS.

To the Editor of THE LANCET.

SIR,—I was about to publish the results of 300 cases of tonsillectomy as practised by me since 1907, when I read the article by Mr. G. E. Waugh in THE LANCET of May 8th, 1909, and I hasten to publish my results and the method of my operation. There is practically very little difference in the technique adopted by Mr. Waugh and myself. Mr. Waugh does not say from what year he has been practising the method he advocates in the article referred to above. As regards the number of tonsillectomies performed by him up to the date of his publication I must admit that he has done three times as many as I have. But considering the population in London and the climatic conditions favourable for throat affections prevailing there, I do not consider that the number of cases operated on by me, mostly in Bangalore with a population of two lakhs or so, compares unfavourably.

The operation hitherto practised in Europe, so far as I am aware, has been the removal of enlarged tonsils by the guillotine. The cases suitable for guillotine are large tonsils causing difficulty in swallowing and breathing. Such cases were placed on the dental chair and under the influence of nitrous oxide gas the tonsils were guillotined within a minute or two. I have also seen such enlarged tonsils guillotined without any general or local anæsthesia, much to the suffering of the unfortunate patients. This was done at the London Hospital out-patient department by a young and energetic clinical assistant who is no longer there. I refrain from mentioning his name, but when his chief asked him if he would do an operation like that on his own son he gave up this practice, at any rate at the hospital.

Of the cases operated on by the guillotine I have seen several in which the whole tonsil was removed satisfactorily without a vestige of its structure being left behind, but the cases in which a part of the tonsil was left behind after this operation had been many. As these cases were mostly out-patients, I had not the opportunity of following their after-history, and therefore I am not in a position to say how far the tonsillectomy with the guillotine method has proved successful.

But since returning to India I have made a close study of my earlier cases operated on by the guillotine method, and to my gr [illegible] nd that the guillotine was not [illegible] ajority of my cases. In such [illegible] diseased and septic, giving ris [illegible] and pharyngitis and otherwise interfering with the general health of the patients, were not large enough for the application of the guillotine. Besides, the Victoria Hospital, Bangalore, is not provided with a dental chair, and the facility for the administration of nitrous oxide gas is not very great in India. All operations which are not amenable to local anæsthesia or to spinal analgesia have to be performed under chloroform. My earlier cases operated on by the guillotine under chloroform in Colombo and in Bangalore failed to give me any satisfaction. I had to draw the tonsils out with a small pair of vulsellum forceps after adjusting the guillotine and in most cases only a small fragment was thus removed. It appeared to me that the game was not worth the candle. Sometimes the guillotines failed to work, being very blunt, and owing to the want of facility to get them sharpened they had to be sent to London to the manufacturers. This entailed long delay. Under these circumstances it occurred to me that a much simpler operation could be performed without the guillotine and with much better results. Since then I have performed about 300 cases in private as well as at the hospital after the method advocated by Mr. Waugh with slight modification, though I was completely unaware of his method until I read of it in THE LANCET.

The methods I adopt for the removal of tonsils vary with their size and with their association with adenoids or not. In the case of large tonsils in adults I still employ the guillotine under local anæsthesia. The tonsils are swabbed over with a solution of cocaine (10 per cent.) and injected through a hypodermic syringe with a syringeful of either cocaine or novocaine with adrenalin at several points. The solution usually employed for injection is novocaine or cocaine grs. 10, adrenalin ʒi, aqua dest. ad ℥i. Within ten minutes the patient is ready and the tonsils are removed with the guillotine almost entire. Sometimes I use the vulsellum forceps to draw the tonsils out of their bed to engage in the grip of the guillotine. Where the tonsils are not much enlarged though diseased, instead of the guillotine I employ a pair of vulsellum forceps and a pair of curved blunt pointed scissors for their removal; the mouth, of course, is kept open by a gag and the patient is seated on a chair. But in the case of children with diseased and enlarged tonsils who are also invariably subject to adenoids, local anæsthesia is not to be recommended for two reasons. In the first place adenoid growths cannot be successfully anæsthetised by such local measures as swabbing or spraying with solutions such as cocaine or novocaine and adrenalin without much discomfort to the patient, as the growth is situated in the naso-pharynx. Any attempt at such a procedure will lead to much retching and vomiting and to great waste of time when one has several cases to get through. Even if local anæsthesia is complete, the sight of instruments is quite enough in the case of children to produce such a fright as to prevent one from performing the operation. Therefore in the case of children I always employ general anæsthesia and choloroform is the anæsthetic used invariably in India and Ceylon. In operations on the throat and nose the anæsthetic is not pushed to the same extent as required for operations on other parts of the body. Anæsthesia is not necessarily complete. Having partially anæsthetised the patient, the head is allowed to hang well over the edge of the table. The mouth is opened by a gag and the tongue is drawn well forward by a stout silk thread passed through the tip of the tongue. The operator stands behind the head of the patient and draws the tonsil out with a pair of small vulsellum forceps. One disadvantage with the vulsellum is that the diseased tonsillar tissue is likely to give way when pulled out, as it is very friable. A conchotome appears to be preferable, but I have had no experience. I do not use any fine-toothed forceps to mark out the preliminary incision. I think it is quite unnecessary and can be easily left out. Besides, it is not absolutely necessary to define the capsule before the removal of the tonsil. If any pieces are left behind they can be felt by the finger and removed by the scissors or by the punch forceps. Pulling the tonsils by the vulsellum towards the middle line, I begin by detaching the anterior pillar from the underlying tonsil with a blunt-pointed curved scissors, and the whole tonsil is removed. In some cases a piece of tonsil extends down the wall of the pharynx and its removal is easily facilitated by this method, whereas by the guillotine it is not at all possible.

One drawback to this method of removing the tonsils is the hæmorrhage which follows in some cases. It often struck me that the amount of hæmorrhage was out of proportion to the quantity of tonsillar tissue removed. But with the head well hanging over the edge of the table and with the mouth wide open, the hæmorrhage is easily controlled with hot sponges on holders and there is hardly any risk of blood entering the larynx. I have so far never met with any casualty. In Mr. Waugh's experience there has been "practically no bleeding," and he accounts for this by the complete anæsthesia employed for his cases to abolish the laryngeal reflex. He states "the absence of bleeding forms a striking contrast to the sharp hæmorrhage which ensues after the tonsil has been cut across by a guillotine." But my experience has been otherwise. In some cases in which the anæsthetist had accidentally produced complete narcosis I still noticed a fair amount of hæmorrhage. I think the position of the head hanging well over the edge of the table is responsible for the bleeding, as it tends to engorge not only the pharyngeal plexus of veins but also all the blood-vessels of the head and neck. With this exception this position gives one a much better view of the field of operation as the light is not obstructed; there is much less chance for the blood to be sucked into the air passages. Hæmorrhage must necessarily follow any cutting operation of a vascular organ like the tonsil which has five vessels of supply, but in this position it is more efficiently controlled, and the operator is not cramped for want of sufficient space for manipulation. Any of these advantages must be limited with the position recommended by Mr. Waugh. In any case hæmorrhage never lasts for any length of time. It is soon over.

With regard to the after-history, I have so far had no casualty and no trouble with sepsis, except in one case in which one of the submaxillary lymphatic glands suppurated and required an incision. This was in the case of a Brahmin girl very much run down, who was not seen by me after the operation until after the abscess had formed.

The after-treatment consists in swabbing the wounds frequently with a solution of cocaine grs. 10, acid. carbolic. ♏ 10, glycerine and water āā ℥ss. The swabbing is done before and after a meal especially. A gargle of a dessert-spoonful of Sanitas in a tumbler of tepid water is also prescribed. I never had any occasion to prescribe anything internally. The temperature on the first day has never gone above 100° F. The patient is confined to bed for 48 hours and fed on slops; solid food is allowed as soon as he is able to take it. Within a week the wounds heal up, while I have never had any occasion to send my patients to the dentist before the operation as the teeth of the people in this part of the world are sound.

As regards adenoids, I find simple curetting is not satisfactory. For median growth curetting is no doubt sufficient, but one finds frequently adenoid growths on the sides and below the entrance to the Eustachian tubes. Such growths cannot be tackled by the curette, and the attempt may be productive of harm. The adenoid punch forceps are best suited for such cases and they can be easily worked with one finger in the naso-pharynx as a guide.

I am, Sir, yours faithfully,
H. B. MYLVAGANAM, F.R.C.S. Eng.,
Surgeon to Victoria Hospital, Bangalore.
Bangalore, June 16th, 1909.

MERCURIAL INUNCTION IN EARLY TABES

To the Editor of THE LANCET.

SIR,—During the past year I have had under my care a number of cases of early tabes, whom I have treated by submitting them to a prolonged course of intensive mercurial inunction, together with sulphur waters used internally, exactly in accordance with the methods followed at Aachen. The patients experienced but slight inconvenience and were in most cases able to attend to their ordinary duties. I have been impressed with the excellent results obtained. In many of the cases the drug had previously been taken by the mouth for long periods, with but little, if any, benefit. Not only, it appears to me, is this method much neglected in this country but the technique would seem to be imperfectly known. It may be added that the Wassermann test frequently confirms the necessity for treatment, as well as affording objective evidence of its effect, and this before improvement is manifested subjectively. I append very brief notes of two typical cases.

CASE 1.—A man, aged 50 years, acquired lues 30 years ago; mercurial pills taken for two years. For the past six years has had lightning pains, girdle feeling, Argyll-Robertson pupils, and exaggerated knee-jerks. During this period has taken several courses of mercury by the mouth without benefit. The Wassermann reaction was positive. After a course of 100 inunctions the serum test became negative and three months afterwards the sensory discomfort had almost disappeared. His appearance improved marvellously, and while gaining in weight his activity greatly increased.

CASE 2.—A man, aged 60 years. Acquired lues 40 years ago, and was carefully treated. Complained of shooting pains, slight ataxia, and numbness in the lower limbs, existing for two months. The knee- and ankle-jerks were absent. At the end of a course of 60 rubbings both knee- and ankle-jerks returned, and two months after cessation of treatment he was free from discomfort, had put on a stone in weight, and felt better than he had done for years.

I am, Sir, yours faithfully,
Wimpole street, W., August 3rd, 1909. REGINALD HAYES.

VENTILATION IN THE TROPICS.

(FROM A CORRESPONDENT.)

So much of the deterioration of the health of Europeans in the tropics is due to the defective ventilation of their dwellings that this subject demands much more attention than it has hitherto received.

The Englishman from London landing in Bombay encounters a climate the mean temperature of which (79·13° F.) is 30° higher than the one he has left, and the mean amount of moisture in the air is 1·135 pounds per 1000 cubic feet as compared with that of 0·51 pounds in London. The average human body must get rid of 284 units of surplus heat per hour in order to maintain its normal temperature of 98·4° F. with a range of half a degree, and as a hot atmosphere retards the cooling of the body, especially if it be also moist, its movement must be increased in order to produce a feeling of comfort, and the circulation should act over the whole of the body. Away from the coast, with its moist sea breezes and moderate temperature, the hot dry air and part of the light are excluded from dwellings where women and children spend their day, and from offices where men work, the circulation being impeded in some cases by wet screens and in others stimulated by fans in connexion with the screens, but no general hygienic system is observable in these methods and no measure of either light or air supply is discoverable. The air of dwellings is frequently hotter both by night and day, and much less pure, than it would be in a plantation of trees.

The ventilation of dwellings in the tropics presents features that are totally distinct from those of cold or temperate countries; this is proved by the failure of appliances, successful in Europe, that are brought out from time to time to be attached to buildings in hot countries. These inventions depend for their efficiency almost entirely on the movement of the wind, either to produce an induced current by being directed past the outlet of the ventilators or by acting on a rotating head to turn a helix which is intended to pump the air out of a building, and thus cause a renewal of the supply. The warmer the air in the building the greater the need of active ventilation, but in India the period of greatest heat is generally accompanied by a dead calm, which affords no assistance to the ventilator and renders it less efficient than a plain opening. Around the coast line, where the air is generally moist and the temperature rarely reaches 98° F. in the shade, the air within doors is warmer than the atmosphere outside owing to the absorption of the sun's heat by the building, whilst in the plains far from the influence of the when the hot dry air out of doors during the day is so much above the indoor temperature that it is excluded as much as possible. Buildings are also made much heavier, and many are lined with sun-dried bricks to act as an insulator against the penetration of the sun's heat. The closing of the buildings is, of course, unwholesome for the inhabitants, the richer portion of whom build large chambers to retard the fouling of the air, but as excreta escape in much greater quantity from the skin in hot countries than in temperate climates, and as the escape of surplus heat takes place chiefly by evaporation when the air is hotter than the blood, the atmosphere of a closed house is liable to become very impure and unwholesome.

The difference in the air of the plains and of the coast has already had its influence on the construction of houses, but as they are principally owned and built by natives of the country tradition has much more influence than science on the construction, and even if a European architect is employed the owner will insist on the carrying out of his own ideas, and his ideal is chiefly remarkable for the number of openings his building may possess without being ventilated. The typical bungalow is a large building under one pyramidal roof without a single ventilating opening through it. The roof extends to the verandah and is covered with tiles which become very dark with age and absorb heat freely from the sun. The heat is radiated downwards through the ceiling boards or ceiling cloth to the tenants whose ordinary protection is a swinging punkha which accelerates the passage of heat from the ceiling by a downward draught. The heat of the tiles continues to radiate downwards far into the night, although the outer air may be pleasantly cool, and the building has hardly cooled to a comfortable temperature when the sun is again upon it. For cooling the air, a hand-driven fan is used to blow it through a wet screen composed of fine fibrous roots woven into a loose mat, which reduces the air passage to 20 per cent., and as there is no means of regulating the proportion of humidity in the current it is generally too damp, and is dangerous on that account.

The writer once occupied a bungalow in Cawnpore having a [illegible] ound it. The walls, [illegible] tewashed, while the [illegible] with dead fungoid growth which caused them to heat up until it was scarcely possible to sit on the parapet wall at sunset. There was no opening for ventilation anywhere above the windows, and the building offered an excellent opportunity for experiments. A 22-inch square hole was cut in the roof of the largest room and a 10-feet chimney of the same form was fixed on the opening. It was made of the thinnest sheet iron procurable, and was unpainted. It exposed 73 square feet to the light, one half of which received the direct sun's rays. A slight dust haze filled the air at the time when the following observations were made at 2.30 P.M., the hottest period of the day: Temperature of the air in the room, 97° F.; temperature of air issuing from the shaft, 113° F.; increase of temperature in the shaft, 16° F.; velocity of current, 133·2 feet per minute; volume passed per hour, 26,553 cubic feet. The movement of air continued night and day with varying velocity according to the difference of temperature in and out of doors. Within, the air was always fresh and pleasant, and a good coat of limewash effectually reduced the absorption of heat by the roof. The chimney shaft when lying on the ground was found to acquire a temperature of 154° F., and had it been coated with a dead black it would have approached the sun temperature at the time, which was 163° F. This experiment does not seem to have been utilised anywhere else, although it offers a cheap and simple remedy against heat and stuffiness indoors.

In the same house was an office room floored with porous bricks, well pointed with good mortar. Each morning seven and a half gallons of water were poured on the floor and absorbed. This water evaporated during the day into the air of the room. The following readings were taken of the wet and dry bulb hygrometers at noon:—

	Dry bulb.	Wet bulb.	Humidity of air
On verandah	103° F.	89° F.	56 per cent.
In office	88°	85°	87 ,,
Difference	15°	4°	31 ,,

The doors of the room were frequently open, the air was kept in movement by means of punkhas, and the office staff had excellent health.

In hot weather the difference of temperature of the air indoors and out is comparatively small, and as that difference is all there is, in the absence of wind, to produce a current, vertical openings alone are effective in India. A club in the North-West Province furnishes a good example. The billiard-room was lofty; it had clerestory windows beneath the eaves in addition to many doors and windows, but at night the heat of the lamps and the players made the room intolerable in hot weather. A smoke experiment showed that the clerestory windows were practically useless, so a 2-foot hole was cut in the middle of the terrace roof and an 8-foot light iron shaft was fixed in it with a suitable cap. The heat of the lamps produced a strong current and there was no further trouble on account of imperfect ventilation.

In Bombay there is great activity among the building trades and land has risen to an abnormal value. Houses are now built in blocks of many storeys, but although the storeys average from 12 to 14 feet in height, the air is dead for several feet above the windows, and ventilation is further restricted by sun screens descending for three or four feet from the verandah roofs. If the dwellings are in flats the chances of perflation are *nil*, and the tenant contents himself with churning the air of his rooms by the aid of electric fans or punkhas. In England a current of six inches per second can be borne with comfort at 65° F., but such a current would be useless in Bombay in May at a temperature of 89° with 75 per cent. of humidity. Under such conditions one may sit with comfort in a current of three feet per second, and the chief business of life seems to be to get rid of one's surplus heat at a sufficient rate. Indian courts of justice have long been notorious for imperfect ventilation and for the odour of unwashed humanity that pervades them. Surrounded by verandahs and corridors that swarm with pleaders, litigants, witnesses, and hangers-on, silence in court can only be obtained by closing the doors. Work of all kinds in such courts is exhausting, and it is a constant marvel that the Government should allow its highly trained officials to work in such places. A moderate structural alteration would enable these rooms to be ventilated through floor and ceiling with upward currents, allowing the doors to be closed and the noise to be excluded. Ventilation, in so far as it applies to the human being, means a supply of fresh air sufficient for respiration, for the removal of the vapours of the skin and lungs, and also of the surplus heat of the body. In the tropics the removal of surplus heat demands more air than all the rest, and a constant current of adequate velocity is necessary to ensure health and comfort. The necessary velocity of the current depends a good deal on the amount of clothing worn. This in the case of the European is nearly always excessive when indoors, for the current required to carry off his surplus heat through his body clothing is liable to cool his head too much and cause a catarrh. The same difficulty arises at night through the use of a mattress which accumulates heat on the underside of the body. A man who can sleep comfortably on a cane chair in the afternoon, dressed in light cotton clothes, finds sleep almost impossible at night with a lower temperature and still lighter clothing, but it does not occur to him to reduce his bedding until he feels the same temperature above and below. There is a further advantage with the reduced bedding, which may be at times no more than a blanket and a sheet on a canvas cot: he may sleep in a moderate draught with impunity as his body is cooled equally all round. The sense of oppression due at times to the use of a mosquito curtain is diminished or removed by a judicious reduction of bedding, for an ordinary curtain will arrest one-half of an air current that would ensure comfort to the sleeper. The chimney shaft already described is a very useful bedroom ventilator, as its current varies with the daily temperature, and although it cools a room by the circulation of air from without it cannot produce an excessive draught as might a ventilator with a constant motive force. The air-supply passed through a chamber by means of this shaft may be drawn through a wet screen like that attached to the thermantidote, but as this arrangement causes an excessive increase of moisture by lowering the dew point and also by direct evaporation, it is better, when possible, to draw the air-supply through a narrow horizontal shaft of zinc cooled on the outside with a wet jacket. This shaft may be made of cheap zinc or galvanised sheet with a section of 8 by 30 inches, and of a length proportioned to its duty. It is supported by a light exterior frame of wood and covered with the coarsest cotton cloth which is kept moist by means of a long trough with wicks or suitable leak holes. Air drawn through this shaft is cooled without additional moisture, and it offers much less resistance to the current than a wet screen of *Kus-Kus*.

The introduction of electric current in our large cities has simplified the possibilities of good ventilation, but so far the only result has been the substitution of revolving electric overhead fans for the overhead punkhas, neither of which renews the air-supply. There is not in all India a properly ventilated public building in which the air-supply is renewed and cooled to suit the requirements of the season and the occupants. In the large hospitals many lives might be saved of patients whose condition does not permit of their removal if the air of one or two private rooms were modified to correspond in humidity and temperature with that of the nearest hill station. The cost in electrical current to reduce 5000 cubic feet per hour of the hot steamy air of Calcutta or Bombay in May to 75° F. and a humidity of 60 per cent is not excessive nor is the necessary apparatus complicated. In official residences, and especially in public offices, a thorough system of ventilation would not only increase the efficiency of the workers but would also reduce the need for those migrations to the hills that are such an unwelcome drain on the resources of many servants of the Government. Large buildings do not need the multiplication of revolving fans that at present disfigure them. A single fan and motor placed in the highest part of the building, and connected with suitable conduits forming part of the structure, would supply an abundance of fresh air at much less cost than any of the existing arrangements.

SLAUGHTER-HOUSE LITERATURE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE INFLUENCE OF LARGE TOWNS AND LARGE ARMIES ON THE ABATTOIR PROBLEM.—GREAT DEFICIENCY OF COMPETENT MEAT INSPECTORS IN ENGLAND.—WANT OF TECHNICAL KNOWLEDGE IN THE CONSTRUCTION OF ABATTOIRS.—GERMAN, BRITISH, AND FRENCH BOOKS ON THE SUBJECT.

SINCE the world-wide alarm caused by the revelations, first made in these columns, concerning the Chicago stockyards, a large number of books and official documents or Government reports bearing on similar questions have been issued. In fact, an extensive slaughter-house literature has come into being, each author endeavouring to meet the general desire for more precise information concerning the practical measures that should be enforced so as to secure a supply of really wholesome meat. Of course, there is always wholesome meat on the market; the real point is to render it quite impossible for any unwholesome meat to reach the market. When thus defined it must be confessed that perfection has not yet been attained, though undoubtedly there have been great improvements. The fact is that in many of its most important aspects new problems have grown out of modern social, economical, and political evolution. The acceleration of the means of transit has totally altered the conditions of supply, while this has been more recently still further modified by modern methods of cold storage. Then while railways and steamships have contributed to bring supplies from enormous distances, this is associated with the great increase in the size and populations of towns. At the same time small professional armies have been replaced by armed nations. The prospect of having to mobilise some millions of men in a few days has created a meat-supply and slaughter-house problem that was never contemplated in the days of small armies. In England, it is true, we have no great conscript force, and have not provided for the possibility of calling under arms within 24 hours a million or so of men and of having to feed them. This is, perhaps, one of the reasons why in England we are so much behind other nations in regard to abattoirs, and why, on the contrary, Germany, with its marvellous military organisation, has the most perfect abattoir arrangements. The same reason may explain why the State in England has done so little in regard to the inspection of meat, whereas in Germany there is not a mutton chop on the market but is strictly controlled by Government. However, we are at least accumulating a fair amount of English literature on the subject, and it is no longer absolutely indispensable to resort to foreign authors in the original, for some of the most valuable works in French and German receive early translation. We noticed in these columns recently that most important and practical German work Ostertag's "Handbook of Meat Inspection," which has now been admirably translated into English.[1] It is not a mere handbook; indeed, no one could carry so ponderous a volume in his hands for long, but it is an excellent and authoritative work.

More portable and suitable for quick reference is a work by Dr. William Robertson, medical officer of health of Leith. This is entitled "Meat and Food Inspection,"[2] and is the sort of work that can usefully be carried in the hand. Not only is it a useful guide to meat inspection, but there is a full and easy reference to the text of the various laws affecting the meat trade. On the other hand, this book contains little or no information on the great problem of the construction, the management, and the cost of large and small public abattoirs. This is, however, in the main an architectural, a sanitary engineering, and a financial problem. The technician who would be able to devise the building, the draining, and the ventilation of a public abattoir may not know anything at all about the post-mortem examination of cattle or hogs. Dr. Robertson recognises that in England we are insufficiently armed in respect to the machinery of inspection. The greater number of the existing sanitary authorities declare that they cannot afford to retain the services of a duly qualified veterinary surgeon; and, if they could, there are not a sufficient number of duly qualified veterinarians to do all the work. Consequently Dr. Robertson urges that every medical officer of health and every sanitary inspector should perfect himself in regard to meat inspection so as to fill the existing gaps. This does not seem a good suggestion, for the actual staff is rarely sufficient to accomplish fully the task which it is recognised should be taken in hand. Therefore it would be still less able to undertake such additional duties. It is quite obvious that we urgently need in England an increase of expenditure so as to train and then engage a much larger staff of meat and food inspectors than are actually on the field.

As the control of food-supply also involves extensive knowledge of sanitary engineering, of ventilation, drainage, the cleaning and the disinfection of cowsheds, stables, cattle lairs, and markets, as well as of the mechanical appliances for slaughtering, it is much more practical to concentrate all such work in the sanitary department of each local authority. That does not mean, however, that an ordinary sanitary inspector should become a meat inspector, but that a much larger number of veterinary surgeons and of specially trained assistant meat inspectors are urgently needed in this country to work in conjunction with the various sanitary authorities. In regard to the actual number of inspectors required, when describing the abattoir of Stuttgart I related that one chief veterinary surgeon and six fully qualified assistants with special knowledge of bacteriology are employed.[3] The population of Stuttgart is estimated at 260,000, or one inspector for every 37,000 inhabitants. At Manchester, when last I investigated the matter there were three veterinary surgeons and one inspector of meat. There were further one inspector and two assistant inspectors for fish and fruit, who also visited retail meat shops, and there are still some private slaughter-houses.[4] Even if we count all these inspectors, though some of them are not fully qualified and have [illegible] this only makes a staff of seven, just as [illegible] population of Manchester is set down at 543,969, and consequently there is only one inspector for every 77,000 inhabitants. Can one individual watch over and control the meat-supply of 77,000 persons? And there are many places in England that are not as well off in this respect as Manchester. These figures will help to show the use of such a book as that written by Dr. Robertson, for it will aid in training the new inspectors we so greatly need.

"Our Slaughter-house System," by C. Cash, B.A., together with a translation of "The German Abattoir," by Herr Hugo Heiss (London: George Bell and Sons), will assist to teach how to build abattoirs. In dealing with the Coventry private slaughter-houses I alluded to this excellent and well-illustrated work.[5] It contains descriptions and pictures of the abominable private slaughter-houses still existing in England, and notably at Coventry, together with some of the model public abattoirs of Germany. For larger and more elaborate illustrations, reference may be made to a work entitled "Public Abattoirs," by Mr. R. Stephen Ayling,[6] This book, the author states, was written to demonstrate that public abattoirs are not a luxury but an absolute necessity. They are needed, he declares, to prevent cruelty to animals and the spread of disease among men. The author also insists that they can be made self-supporting and profitable, an assertion which my German experience fully confirms. According to this work there are now 131 public slaughter-houses or abattoirs in the United Kingdom. A few of them have been well planned, others are indifferent, "and the great majority bad." There is no such thing as an abattoir system in England, though on the continent efforts to create such a system were commenced a century ago and have now reached a high degree of perfection. There still remain 318 private slaughter-houses in London entailing much cruelty to animals, with waste of valuable material, and defying systematic and reliable inspection. From these places tuberculous meat can be placed on the market with very little chance of detection. Then there are the "screw butchers" who only buy diseased and dying cattle. These animals they cart away from the farms at night and manage to slaughter and sell advantageously the unwholesome meat thus produced. Mr. Ayling also points out that the care given to the health of live cattle is inadequate, and, as a case in point, he mentions that in 1893 the British Government made an allowance of £100 for research as to the value of the tuberculin test to detect the presence of tuberculosis in cattle, while in the same year the Government of little Denmark devoted £2812 for that purpose, and this was continued for five years, when the annual allowance was raised to £5625.

[2] Meat and Food Inspection, by William Robertson, M.D. Glasg., D.P.H. With 40 illustrations. London: Baillière, Tindall, and Cox. Pp. 372. Price 10s. 6d. net.

[3] See THE LANCET, April 18th, 1908, p. 1177.

[4] See THE LANCET, June 27th, 1908, p. 1873.

The principal value of Mr. Ayling's book, as already remarked, is the practical information it contains as to the actual construction of abattoirs. The reason why such [illegible] are for the most part defective [illegible] nerally placed in the hands of a [illegible] real knowledge of this special technical question. He consequently merely imitates the defects of neighbouring abattoirs which he has been able to visit. Thus in one case we may get very good engineering and fittings with no architectural merit, and in another case considerable architectural taste and originality may only serve to cover defective principles and equipment. The matter has received very little attention at the hand of the British architects and engineers. Thus a writer on the subject is mentioned as having advocated a red-brown dado so that the splashes of blood may not be apparent instead of asking for white glazed tiles so that the blood may readily be seen and as rapidly washed off. Not only must the walls be washed constantly but the slaughtermen should be provided with comfortable lavatories where they can change their clothes, have douches or baths, and thoroughly clean themselves. Then, if it is a large abattoir, it should be provided with its own destructor and not built near the town destructor, as the dust from the town refuse will penetrate by the ventilators into the cold storage rooms and other parts of [illegible] Mr. Ayling gives plans [illegible] public abattoirs in Great [illegible] lockyards, South Shields, West Hartlepool, Leeds, Glasgow, and several other British towns. His continental experience, however, seems limited to the Paris abattoirs of La Villette and Vaugirard. These he describes very elaborately, though they are out of date and the Paris municipality is now discussing their reconstruction on better and more modern principles.[7]

A handy little publication, with numerous illustrations that help to show how abattoirs should be built, has been issued by the county borough of Belfast. A deputation was appointed by the Belfast city council last February and March to visit certain abattoirs in England and the continent. It cannot be said that the deputation selected the best towns to visit, nevertheless they saw much that was most instructive. This is how the result of the journey is pithily summarised:—"Rotterdam: An old abattoir about to pass away. Hamburg: Splendid business arrangements. Berlin: The best system of meat inspection in Europe.[8] Dresden: A new abattoir in course of construction. Cologne: A modern abattoir in course of operation. Islington; A new abattoir, spoiled for want of room." In the recommendations based on this experience for the construction of a public abattoir at Belfast the deputation have made good use of their continental experience, though it is a pity that when at Dresden they did not manage to go to Breslau to visit the magnificent abattoir, which only cost 10*s.* 6*d.* per inhabitant, and the cattle market that did not cost more than 6*s.* 6*d.* per head of the population. The receipts of this abattoir amount to £60,000 per annum, and about a third of the sum may be considered as profit. Then in Holland they should have seen the abattoir of Maestricht. Here not German but French equipment and machinery are employed. It is considered about the best abattoir in Holland, while that of Rotterdam is one of the worst. The deputation in their recommendations have shown that they still retain a lingering attachment to the old idea of partitions that separate the butchers one from the other. This is [illegible] Indeed, the only arg [illegible] er-hall is the possible [illegible] animals when admitted may suffer from the sight and smell of blood. This objection has been met at the small slaughter-house built by the Admiralty at the Chatham Dockyards. There would be no objection in following this example. The animals might be killed just outside the door, but only killed. The moment the animal has fallen a door should open and a pulley arrangement should drag it into the hall, and there, and only when in full view of the inspectors, should the carcass be opened and the process of dressing begun. There must be no retreating into corners or standing between [illegible]

[illegible] ter house literature, there a [illegible] issued in France on this subject. "Les Abattoirs Publics," which I quoted when describing the Paris municipal abattoir at La Villette, is a veritable monument of learning and research, not limited to France, but extending through Europe, America, and Australia. The first volume is by M. J. de Loverdo, sanitary engineer, and it has 903 pages, 404 illustrations, and deals mainly with the construction of abattoirs, while the second volume has 648 pages with 110 illustrations and treats rather the question of the inspection of animals and meat. The principal contributor to this second volume is Dr H. Martel, chief veterinary surgeon in the service of the Paris municipality. Dr. H. Martel is likewise the principal author of the very elaborate and interesting annual reports published by the Paris Prefecture of Police on the veterinary sanitary services of the department of the Seine. Here all the details relating to the inspection of the food-supply for the capital of France and the surrounding suburbs will be found. Thus, for instance, we are told, and statistics prove, that the number of cases of tuberculosis among the cattle at the Paris cattle markets has greatly decreased. But this is not due so much to improved conditions as to the severity of the examination of the animals, so that cattle-breeders now know they are not likely to succeed in smuggling diseased animals through. No one can examine this publication without feeling that the French nation, which a hundred ago years stood first and set the best example in regard to the abattoir question, is now fully alive to the fact that the high standard has been fallen away from. But France will soon regain much of the lost ground. It is to be hoped that the time is not far distant when Great Britain will also enter into the lists and endeavour to take a worthy place in this generous competition between nations striving to control to the best advantage the food on which the people live.

THE SIXTH NORTHERN CONGRESS OF MEDICINE.

(FROM OUR OWN CORRESPONDENT.)

IT was originally intended to hold the Northern Congress of Medicine at Bergen in Norway, but partly for political reasons the Norwegian President of the Congress proposed as a more suitable place the Skaw, a bathing resort of no great size in Denmark, and a considerable number of the most prominent medical men in Denmark, Finland, Norway, and Sweden accordingly met here under the presidency of Dr. **KLAVS HANSSEN** (Bergen).

Pulmonary Tuberculosis.

The proceedings commenced with a discussion on the Early Diagnosis of Pulmonary Tuberculosis. Professor **SAUGMANN** of Vejle Sanatorium in Denmark introduced the subject of the ordinary clinical diagnosis, while Dr. **TILLMAN** of the Oesteraasen Sanatorium in Sweden discussed the specific diagnostic methods.

Professor **SAUGMANN** said that the diagnosis was not merely a subtle stethoscopic one, but ought to rely on a general clinical examination. In some cases the diagnosis might be made in the absence of objective stethoscopic alterations, based only on a thorough anamnesis and a complete examination of the whole organism, special attention being paid to signs of absorption of toxins in the fluids of the body. The first objective signs were often to be found by a study of the temperature curve. A useful inference might sometimes be drawn from the so-called Penzoldt's phenomenon—namely, if the rectal temperature after a brisk walk of an hour's duration rose above 38° C. the case was suspicious. As to the stethoscopic signs, the "rough" (*rauhe*) respiration, described by Turban, was often a sound of muscular and not of pulmonary origin. Dr. Krönig had described a simple, non-tuberculous induration of the apex of the lung in chronic nasal obstruction, but this was only a healed or a very chronic form of pulmonary tuberculosis. Searching for tubercle bacilli often gave a negative result; he felt disposed to consider cases in which tubercle bacilli were found as being no longer incipient in the anatomical sense of the word. The diagnosis ought to be made before the appearance of tubercle bacilli in the sputum.

Dr. **TILLMAN** laid stress on the practical importance of the diagnostic subcutaneous injection of tuberculin, particularly when resulting in a local reaction. Complete absence of response to the injection of large doses (10 milligrammes) excluded tuberculosis. The patients must have been free from pyrexia or hæmoptysis for several weeks before the injection. Pregnancy and diseases of the heart or kidney were contra-indications. The tuberculin test was only to be applied when other means of diagnosis had failed. As the occurrence of râles was an important criterion of the positive reaction, the injection ought only to be made on patients without râles. The first dose was one- or two-tenths of a milligramme. If there was a positive temperature reaction an injection of pure water ought to be tried in order to control the result. The local tuberculin tests (that of von Pirquet, or the ophthalmo-reaction) were of no importance for the diagnosis of incipient pulmonary tuberculosis, as they only showed the presence of tuberculosis somewhere in the organism. The agglutination test and determination of the opsonic index have for the time being small practical value.

In the discussion Professor **LAACHE** (Christiania) communicated the result of some researches made by his assistant, Dr. Tillisch, showing the diagnostic importance of abolished or lessened motility of the inferior pulmonary border.

Professor **ISRAEL-ROSENTHAL** (Copenhagen) expressed his hesitation in adopting the subcutaneous tuberculin test as it presented a certain amount of danger in some cases.

In closing the discussion Professor **SAUGMANN** said that the von Pirquet test was not always reliable; he had himself suffered from acute pulmonary tuberculosis 18 years ago, and at the present time responded positively to the ophthalmo-reaction but negatively to the von Pirquet test.

Professor **GRAM** (Copenhagen) read a paper by Dr. **ELLERMANN** and Dr. **ERLANDSEN** on the Production of Sensitiveness to the Cutaneous Tuberculin Test of von Pirquet. Their researches showed that this test sensitised the organism in such a way that the reaction was stronger on repetition of the test than at its first application. The subsequent reaction was a little feebler than the first one in only 8 per cent. of the cases; in 8 per cent. it was unaltered; and in 84 per cent. it was stronger. If the tests were carried out on two successive days there was no difference, but after a pause of four days an increase in the reaction was distinctly observed. Sensitiveness was likewise observed after an interval of several months. This sensitiveness was not a local process, as the new test might be applied to a superficial region of the body at a distance from the region chosen in the first instance. It was only after absorption of the tuberculin that sensibilisation was observed. It was not possible to sensibilise an organism that was quite free from tuberculosis.

Dr. **WURTZEN** (Copenhagen) communicated the results obtained by himself and Dr. Kjer-Petersen in the treatment of pulmonary tuberculosis by the production of artificial pneumothorax. They had treated 27 cases in all, but the formation of adhesions between the pleural membranes prevented the establishment of a complete pneumothorax in more than seven of the cases. In three of the cases the treatment appeared beneficial, and they thought that one case of acutely developing pulmonary tuberculosis was saved by this means, as it seemed at first quite hopeless in all respects. In one case the treatment had arrested a dangerous hæmoptysis. As a rule, however, the pathological process in the other lung at last annihilated the favourable results first obtained.

Professor **SAUGMANN** said that he had tried the treatment for 42 patients, in ten of whom he had not succeeded in producing an effective pneumothorax. In one case the lung was kept compressed for ten months, and when the treatment was discontinued because it was found that the patient's pyrexia was not caused by pulmonary tuberculosis the lung expanded again quite well without having sustained any injury to its function. In two cases that came to post-mortem examination the pathological process was seen to be healing. On the whole, Professor Saugmann found the treatment satisfactory.

Dr. **KR. THUE** (Christiania) said that he thought the treatment was very efficacious in certain cases of advanced unilateral pulmonary tuberculosis. In one instance he had observed pyo-pneumothorax originating from a lung cavity as a result of the forcing of adhesions, and in two instances collapse from a pleural reflex.

Dr. **VON BONSDORFF** (Finland) and Dr. **FIGENSCHOU** (Christiania) corroborated the statement of Dr. Arneth, that a considerable increase in the number of the mononuclear leucocytes accompanied the aggravation of the disease.

Functional Diagnosis of Various Diseases.

The second day of the Congress was taken up by a discussion on Functional Diagnosis. Professor **SCHAUMANN** (Helsingfors) discussed the importance of functional diagnosis as compared with the anatomical diagnosis fostered by the great schools of morbid anatomy in Germany and France.

Dr. **SIGVARD MADSEN** (Bergen) read a paper on the Functional Diagnosis of Heart Diseases. He said that this method of diagnosis was based on an examination of the pulse, respiration, and blood pressure after the patient had performed a definite quantity of work. He did not ascribe great importance to the variations in blood pressure, but relied on an examination of the pulse and respiration After a person had taken exercise equivalent to 300 kilogramme-metres of work the pulse ought to attain its normal frequency in from one-half to three-fourths of a minute, and it ought all the time to allow of being easily counted. The respirations ought not to exceed 20 per minute and ought to go down again to the normal in half a minute.

In the discussion Dr. **RUBOW** (Copenhagen) laid particular stress on the examination of the alterations of the respiration. He said that in patients suffering from heart disease, it was not sufficient to determine the respiratory frequency, as their dyspnœa might show itself in deeper respiratory movements, the characteristic feature being a greater inflation of the lungs than normal.

Professor **P. F. HOLST** (Christiania) and Professor **ISRAEL-ROSENTHAL** said that they were somewhat sceptical as regards the reliability of the examinations mentioned

Dr. **V. SCHEEL** (Copenhagen) drew attention to the fact first mentioned by Quincke, that while in normal persons the diuresis was greater during the day than during the night, the contrary obtained in patients suffering from heart disease as a result of the freer renal circulation in the recumbent position.

The PRESIDENT said that it was of importance to decide whether the heart was able to perform the work actually demanded of it, and that this was best done by taking a walk with the patient. He thought it was possible to judge separately of the function of the right and left sides of the heart. Insufficiency of the right side of the heart produced dyspnœa without alteration of the pulse, whereas this latter symptom was the first to appear in insufficiency of the left side of the heart.

Dr. OLAF SCHEEL (Christiania) opened a discussion on the Functional Diagnosis of Diseases of the Stomach and Intestines. In mentioning the examination of the motor function of the stomach he recommended Faber's modification of Bourget's test meal. The function of the intestines was best judged of by an examination of the fæces while the patient was on a diet of uniform composition, as, for instance, that described by Schmidt.

Dr. VERMEHREN reported a case showing how extremely cautious a surgeon has to be before considering the diagnosis of ulcer of the stomach as perfectly certain. The patient in question was a woman presenting every symptom of ulcer of the stomach. Gastro-entero-anastomosis was accordingly performed, on which occasion a stellate scar and a thickening of the anterior pyloric wall were observed during the biopsy of the stomach. Two days later she died from bronchopneumonia, and the post-mortem examination failed to reveal anything abnormal in either the stomach or duodenum. He suspected that not a few cases reported as verified by operation would on closer examination turn out to appertain to the same spurious class as that mentioned by him.

Dr. VICTOR SCHEEL (Copenhagen) opened a discussion on the Functional Diagnosis of Kidney Diseases. He said that no single test gave reliable information. The degree of albuminuria or the mutual relation between the different albumins was of little assistance, but the determination of the accommodating power of the kidneys was of greater importance. In the test originating with Dr. Kl. Hanssen and Dr. Gröndahl, the patient was given alternately a diet rich in fluids and one in which the solids preponderated; in healthy persons the urine accommodated itself to the quantity of water contained in the food, whereas this faculty decreased with increasing severity of the nephritis. The methylene-blue test was also of some value.

Dr. TALLQUIST (Helsingfors) said that in his opinion functional diagnosis was most important for the differential diagnosis of the various forms of polyuria.

Miscellaneous Communications.

The discussions were followed by a series of minor communications. Professor FABER (Copenhagen) read a paper on the Diagnostic Value of the Estimation of Pepsin in the Gastric Contents. He had used Liebmann's peptometer, and thought the method of some value for the diagnosis of gastritis.

Professor SANTESSON (Stockholm) reported on the Mortality from Pneumonia and Typhoid Fever in Cases treated with or without Alcohol. The greatest mortality was found in those treated with alcohol, but as alcohol was presumably more often given in the severe cases the statistical data did not warrant an opinion unfavourable to alcohol.

Dr. RUBOW (Copenhagen) communicated his researches on the Nature and Treatment of Dyspnœa associated with Heart Disease. He said that in severe cases of cardiac insufficiency an increased inflation of the lungs was observed. While in healthy individuals the volume of respired air was from seven to nine litres per minute, there often was in the cases mentioned a respiratory volume varying from 10 to 15 litres per minute, the result being a higher percentage of oxygen in the alveolar air, and consequently also in the blood, so that in this way the organism brought about a sort of compensation.

Professor P. F. HOLST (Christiania), in a paper on the Action of Digitalis, said that in 40 systematically examined clinical cases he had failed to observe any difference in the action whether he used old or new digitalis leaves; neither had he observed cumulative effects.

Professor AXEL HOLST (Christiania) communicated experimental investigations made by himself and Dr. Frolich on the Cause of Scurvy and Beri-beri during Sea Voyages. He was inclined to accept Nocht's theory that the latter disease, so often observed in Norwegian ships, was related to scurvy and was caused by deterioration of the food. Guinea-pigs fed on a diet tending to cause scurvy developed a disease in all important respects similar to beri-beri as met with on board ship when, besides the food mentioned, they were [illegible] out [illegible] that [illegible] ased [illegible] sted [illegible] ina- [illegible] the human subject.

THE TERRITORIAL MEDICAL SERVICE.[1]

(*FROM A SPECIAL CORRESPONDENT.*)

III.—THE SANITARY UPKEEP OF CAMPS, &C.

BEFORE camps or bivouacs are entered upon concise orders as to the conservancy arrangements connected with latrines, urinals, disposal of refuse, sullage water, &c., must be framed by the medical officers concerned and issued in the name of the officer commanding to all units. Orders in themselves are useless unless intelligently interpreted and understood, and it must be impressed on all concerned that the fighting power of an army depends on its health, and that the general health of the army depends on the strict observance by the individuals that help to form it of the orders promulgated, more especially concerning the following: 1. Each man that uses a latrine must cover his dejecta with dry earth. 2. Each man must use the urinals provided; if found urinating within camp boundaries elsewhere, either by night or day, he should be severely punished. 3. All refuse, horse litter, and sullage to be removed from camp daily and disposed of.

Latrines.

Before occupation of a camp the medical officer with the advance party should mark off with flags the position of the latrines. The site should be to leeward and the trenches should be so planned as to lie in echelon on the outward flank on an area not likely to be flooded by storm water from higher ground, and well away from the water-supply (river, ponds, wells, &c.) and at least 100 yards from either the nearest tent, ablution place, cooking place, or slaughtery. In the case of some of the Territorial training camps which are situated near towns the dry-earth disposal system may be in force, being carried out by contract. In this, latrine seats are provided, and there should be two sets of buckets to allow of replacement of those removed nightly for emptying and cleansing. In the dry-earth system it is essential that the earth should be finely sifted (through half-inch mesh sieves) and thoroughly dried before use. When trench latrines are used the system of long deep trenches formerly employed is not to be recommended, as they are offensive and attract flies. The ground in front of the trenches from their frequent use become sodden with urine, and mud gets carried back into camp on the men's boots. If infected by a typhoid carrier with bacilluria this mud may cause an outbreak of enteric fever in the camp.

During recent years the shallow system of latrine trenches has been employed at manœuvres in some places and has given good results. The trenches are small and shallow, being 3 feet long, 1 foot broad, and not more than 2 feet deep, generally 1 foot being sufficient. The number required is approximately 5 per cent. of strength per diem—e.g., five trenches will meet the requirements of a company of infantry for one day. These trenches should be arranged in parallel rows (in echelon) with an interval of not more than 2 to 2½ feet between each trench. This distance is important, as being limited it makes the man use the trench properly and it cannot be used otherwise than in a "bunker" position, and thus a spillage of urine on the grass or soil in front of the trench is avoided. When the first trenches are filled with excreta to 6 inches from the surface they are closed in and fresh trenches may be dug in the interspaces, if space is limited, otherwise it may be better to use a fresh area. In digging these trenches the surface grass sods are carefully raised in sections and laid on the grass at a short distance away; the earth is then cleared out of the trench and piled in a heap either behind the trench or at its end farthest away from camp. The earth on the top of this heap is pulverised with the spade and finely sifted to have it ready for use, and a trowel or scoop (easily improvised by tin cans or pieces of board) laid on the top for each man to cover his dejecta with. If the camp or bivouac is likely to be occupied for any length of time the area for the first trenches to be used should be farther away to allow of fresh ground being taken up between those to be first used and the new ones, thus preventing men from walking over soiled ground and perhaps carrying urinary infection into the camp. In planning measurements for a trenching area for a company, allow a front of 12 feet and a depth of 24 feet for each two days; this will give sufficient room for passage to and from the trenches.

---

[1] Nos. I. and II. were published in THE LANCET of July 31st and August 7th.

Strict sanitary instructions must be issued. Men should be ordered to put a few scoops of the dried pulverised earth on their dejecta after using the latrine. The sanitary police should patrol the area and defaulters should be severely punished. Latrine paper is to be kept in tin boxes and to prevent it blowing out of the trenches after use in windy weather a latrine screen should be set up as close as possible to the trenches, leaving, however, a space of three feet between it and those in use. In some camps a light hand rail is placed about two feet off the ground. It is not, however, necessary. The length of time shallow trench latrines may be used must depend on weather conditions and amount of ordure; generally two days, or, perhaps, four may be allowed if well covered by finely sifted earth and if the contents of the trenches which tend to get heaped up in the centre are levelled. In closing the trenches after levelling the contents the clay should be closely packed in and hammered tightly if space allows and if the contents are not liquid. After closing, litter, brushwood, or rubbish should be burned over the entire surface of the trench to sterilise any spillage. The grass sods should then be carefully replaced and the position of the covered trench marked with flags to prevent accidents to passers-by or horses. When on the march with troops company officers should detail men to dig a trench at each halt similar to that described, and before starting again it should be covered in with clay. Spades should be carried for this purpose in each company, and not in their wagons, the kits of the men carrying spades being carried in the wagons instead. When camp is reached the latrines could be dug at once without having to wait for the baggage to come up. Men should not be allowed to fall out until the latrines have been reported to company officers "as ready" and their position indicated by a distinguishing flag pointed out to the men. Outposts and men on picket duty must be made to provide themselves with latrines also. All latrines must be personally inspected daily by the officer in sanitary charge of each unit.

Urinals.

This is a much more difficult subject to deal with in camps and bivouacs from a sanitary point of view than latrines, as owing to the distance of the day urinals from camp a separate set closer by may have to be arranged for night use.

Day Urinals.—For day urinals, pits or trenches may be dug adjacent to the latrine trenches. If the soil is a sandy or absorbent one the urine soon disappears and all goes well, but if not, a urine-sodden quagmire results, which clogs the men's boots and is carried back into camp, and if infected by a typhoid carrier with bacilluria enteric fever might result. In all cases exposed urine-sodden soil must be covered at least once daily with clean dry earth to protect it from flies. Urine trenches wherever possible should, like latrine trenches, be dug to leeward in echelon on the outward flank of the camp on a site not likely to be flooded by storm water from higher ground, well away from the water-supply, and, when the ground allows it, at least 100 yards from the nearest tent, cooking place, or slaughter place. The trenches should be shallow, three or four feet deep, and the earth at the bottom well loosened. If the camp is to be occupied for a week or ten days the trenches should be from four to five feet deep, since the use of shallow trenches will only result in a larger extent of surface pollution. Urine trenches should be disinfected daily by burning in them a layer of dry litter. Tilbury-Brown made trials at manœuvres of a system of shallow urine trenches leading into pits filled with large stones. A circular pit three feet deep and two feet wide was dug, and this was filled with large stones. Two trenches six feet long and having a fall of one inch for each foot to the central pit were dug at an angle to, and running into, the central pit, the sods being carefully removed and the soil heaped up around the central pit, which was also screened off with a circular screen to prevent the men from using it. The trenches were used for about two days, and when foul they were filled in and new ones dug round the central pit like the hands of a clock. The entrance opening in the outer screen was moved round as new trenches were dug, so as to compel the men to enter only between the trenches in actual use. The results were satisfactory and preferable to the usual open pit; surrounding ground was little fouled and many men could use the trenches at the same time. Smell and flies were absent.

Night Urinals.—These are still more difficult and dangerous to deal with than day urinals in camp. They must be easy of access, only a short distance from the sleeping quarters, and easily found, their position being indicated either by a lantern, a white post, or by a path marked out with stones, preferably white, to enable the soldier to find his way thither in the dark. Firth recommends when urine tubs cannot be provided, or when the day urine pits are any distance from the men's tents, the digging of shallow urine pits near the men's lines, but says that this practice should be resorted to as rarely as possible and must be zealously safeguarded against abuse, and at all times such pits should be carefully filled in at dawn McGill also, from service experience, recommends that night urinals should be located in the space between the perimeter and the outer line of tents on the side opposite to the cooking places, their position being indicated by a lamp or white post In standing camps receptacles may be used (empty kerosine oil tins), being taken into use at nightfall and removed at *reveille*, when the sites on which they were placed should be cleaned and disinfected with burning litter or a strong solution of chlorinated lime. In temporary camps, where receptacles are not available, McGill recommends the digging of a few broad shallow trenches filled with 3 to 4 inches of dry litter, or better still, wood ashes, this being removed and buried after dawn and the trenches disinfected. Tilbury-Brown, in the camps at the Hampshire manœuvres, used wooden tubs for night urinals; these were placed along the streets and flanks (not in the lines) and by the side of whitewashed posts upon which lights were hung at night. In many cases stands were made for the tubs. Four tubs were placed outside the canteen. The tubs were emptied during the time they were mostly used—i e., at 10 P.M. and *reveille*. They were not emptied into the day urinals, but into special soakage pits. During the day-time the tubs were either inverted or filled with water. During field operations small shallow urinals were dug every night, one for each half battalion, and a light was placed by each, and they were filled in each morning. The results were very satisfactory. During the South African war the subject of night urinals gave the writer considerable trouble, and he adopted the simple plan of having a 3-foot circular pit dug at each corner of the regimental bivouac with a pile of stones erected beside it for a land-mark and a line of large stones as a guide to its position from the nearest place occupied by the men; sometimes white stones (quartz) were available. The pits were sprinkled with clay each morning to keep away flies, and were filled in when fouled and fresh ones dug. In standing camps, beer barrels were obtained and sawn in half, forming tubs; these were removed in the morning, and after cleansing were treated with strong disinfectants.

Cooking places.

These should be located on the flank or the side of the camp opposite to that near the latrines and the urinals, and on no account should a cookhouse be less than 100 yards from the nearest latrine or urinal; in fact, the farther they are away the less the chance of contamination of food-supplies by flies and dust. The cooking places and their vicinity must be kept scrupulously clean, and neither kitchen refuse nor sullage water is to be thrown on the ground; the former should be collected in buckets and buried outside the camp perimeter daily. In order to separate the grease from kitchen sullage, some authorities recommend the construction of small intercepting grease pits made with sticks, straw, grass, or heather, which can be removed daily and burnt. Special attention should be directed to the means and methods of storing food preparatory to cooking and also to the proper cleansing of the cooking utensils.

Refuse disposal.

No rubbish of any kind should be allowed to lie about in the camp or its vicinity. To collect small rubbish, pieces of orange peel, bits of paper, &c., a good plan is to have empty sacks, or barrels, or boxes with moveable lids placed at the end of each row of tents. These can be cleared out periodically and the contents *burnt* well away from camp or over the latrine or urine trenches before the surface sods are replaced, thus being utilised for sterilising purposes. Litter or refuse in general should not be buried if it is possible to destroy it by fire. In stationary camps, destructors or incinerators if fuel is available will prove a boon, but failing these a ready and effective method is to throw up a bank of earth in the shape of a horseshoe 2 or 3 feet high, and to burn the litter inside; this method has been employed in Indian frontier expeditions with success. All litter and refuse must be disposed of *daily* to obviate the attraction and breeding of flies.

The daily disposal of excreta and also of refuse constitutes one of the golden rules of camp sanitation.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The William Mitchell Banks Memorial Lecture.

BY invitation of the Council, Senate, and Faculty of Medicine of the University of Liverpool, Professor Harvey Cushing of the Johns Hopkins University, Baltimore, U.S.A., on August 4th delivered the fifth William Mitchell Banks memorial lecture in the surgical theatre of the Medical School of the University. There was a numerous gathering of members of the medical profession and students. Mr. K. W. Monsarrat, the dean of the Medical Faculty, presided, and introduced the lecturer in appropriate terms. Professor Harvey Cushing chose as the subject of his address "Recent Observations on the Pathology and Surgical Treatment of Intracranial Tumours." He referred in particular to the results of palliative and radical operations performed during the previous ten months on 64 cases. He detailed first the symptomatology of the affection, and drew particular attention to the alterations in the fields of vision and of colour vision as among the earliest observable phenomena. In dealing with the morbid anatomy, he went into detail regarding the experimental work which had been done to demonstrate the functions of the pituitary body, and showed how over-action was associated with the phenomena termed acromegaly, and under-action with a characteristic form of obesity and sexual infantilism. He described a case of removal of the pituitary body from an acromegalic. In the third place he demonstrated by numerous lantern illustrations the methods of operative technique which were employed in his clinic. At the close of the lecture he said that he felt more deeply than he could express in words the full obligation which that occasion had imposed upon him—an obligation not only in view of the compliment of having been asked to deliver the William Mitchell Banks memorial lecture, but also in view of his feeling of responsibility to reward his hearers in a measure for their generous attendance. He was glad to lecture under the auspices of the University of Liverpool in honour of one who, as anatomist and surgeon, was a devoted Æsculapian in Liverpool, and whose life and works were well known in the daughter country over the sea.

New Hospital at Hoylake.

On July 15th the Lord Mayor of Liverpool undertook a journey to Hoylake and West Kirby for the purpose of fulfilling two interesting official engagements. At Hoylake his lordship, who was accompanied by the Lady Mayoress, was present during the laying of the foundation-stone of the new Hoylake and West Kirby Cottage Hospital by Sir Thomas Royden, Bart., the erection of which has become necessary owing to the inadequacy of the existing hospital at Hoylake for the needs of the district. The committee, at a cost of £1000, has secured what it considered to be the best available site—a plot of ground comprising about five-sixths of an acre situated at the corner of Birkenhead-road. The hospital will be above the road level and will have accommodation for 16 beds. The building will be placed angle-wise on

From

ng-hall

access

to the male and female wings. In both these wings will be two wards, one containing six beds and one two beds, both of which are to have exits to an open verandah. Sanitary blocks, which will be fitted with appliances of the most up-to-date type, are to be introduced close to the wards, but effectually isolated by short "cut-off" corridors. Favoured fortunately by sunny weather, the ceremony of laying the foundation-stone attracted a numerous attendance. The Lord Mayor explained that the new hospital was intended to serve as a memorial of the late Queen Victoria, and remarked that there could be no more fitting reminder of one who had been so closely associated with the nursing movement. The Lord Mayor and Lady Mayoress then paid a visit to the Children's Convalescent Home at West Kirby.

The New Medical Officer of Health of Chester.

Dr. J. R. Currie has been appointed medical officer of health of the city and county borough of Chester in succession to Dr. A. E. Thomas. Dr. Currie, who is a graduate in medicine of the University of Glasgow, was for some time senior assistant physician at Belvidere Fever Hospital. In 1907 he acted temporarily as medical officer of health of the counties of Stirling and Dumbarton in the absence of the medical officer of health, and towards the close of that year he was appointed assistant medical investigator under the Royal Commission on the Poor-laws. During the past year Dr. Currie has been assistant medical officer of the city of Chester.

Liverpool School of Tropical Medicine: Appointment for Dr. Anton Breinl.

Dr. Anton Breinl, of the Liverpool School of Tropical Medicine, has been appointed to the directorship of the newly founded School of Tropical Medicine in Western Australia. For many years Dr. Breinl was first assistant to Professor Chiari in Prague. He joined the Liverpool School of Tropical Medicine in 1904, having been appointed to the Johnston International Fellowship. He shortly afterwards was despatched to Manaos as a member of the school's yellow fever expedition. He and his colleague both contracted yellow fever during their investigations into the causes of that sickness, Dr. Breinl, after a very severe illness, being invalided home to England. Dr. Breinl is chiefly known for his researches on the parasite of sleeping sickness. He and Dr. Thomas first drew the attention of the profession to the value of atoxyl in the treatment of sleeping sickness. His departure from Liverpool will be very much regretted by his colleagues at the University.

WALES.

(FROM OUR OWN CORRESPONDENTS.)

West Wales Sanatorium.

THE delay which occurred in the establishment of the sanatorium for the counties of Carmarthen, Cardigan, and Pembroke possibly served a good purpose, for the experience of similar institutions has proved the desirability of making a careful selection of the cases taken for treatment. During the first six months of the present year nearly all of the 20 beds in the sanatorium have been occupied, and the executive committee is considering the advisability of fulfilling their original intention of erecting the necessary buildings for

were engaged in before they broke down in health, eight have changed their occupation, three though able to work were not obliged to, one has died, and three are following up in their own homes the treatment which they received in the sanatorium. The establishment of the institution met with a considerable amount of opposition, particularly from some members of the county councils, but the results more than justify the action of those who urged its necessity.

Dearth of Water in Swansea.

In October, 1907, there was completed by the Swansea corporation a large reservoir in the Cray Valley, Brecknockshire, with a storage capacity of 1,000,000,000 gallons, and it was confidently expected that the inhabitants of the town would have an ample water supply for many years to come. This anticipation received a rude shock during the last week of July when a large number of houses were placed upon a three hours' daily supply. It has transpired that the cause of this restriction was not the absence of water in the Cray reservoir, but the inadequacy of the conduits for delivering it into the service reservoirs, which themselves received independent supplies from adjacent streams. The low rainfall in the spring months had assisted in the depletion of these reservoirs. It is satisfactory to know that a second line of pipes is being rapidly laid between the Cray reservoir and the service reservoirs, and upon its completion there cannot possibly be a recurrence of the present unsatisfactory conditions.

Glamorgan Water Board.

The attempt of the Glamorgan county council to establish a water board for portions of the county, though successful before a committee of the House of Commons, has failed before the Lords Committee. The proposals of the council included, briefly, the purchase of existing water undertakings in certain districts and the supply of water in bulk to sanitary authorities who would themselves arrange for its distribution. There was opposition from those authorities who were already provided with adequate supplies and who objected to existing arrangements being interfered with. There appeared to be a strong impression, for which there was a certain amount of justification, that the scheme had been promoted in the interests mainly of the Rhondda valleys and of Pontypridd, where there is undoubtedly an inadequate water-supply. In announcing the decision of the committee that the Bill should not be allowed to proceed further the chairman, the Earl of Kintore, expressed the opinion that a comprehensive scheme of water-supply would one day be required for the county of Glamorgan. One result of the decision of the committee will no doubt be that the Pontypridd waterworks, which are situated at the head of the little Rhondda valley, will be purchased by the Rhondda and Pontypridd urban district councils. The former body already possesses extensive waterworks which are now in process of enlargement.

Lupus Patients in Swansea.

There has been placed in the hands of the Swansea Ladies' Samaritan Fund the sum of £1000, the interest of which is to be used for the purpose of providing special treatment for necessitous patients suffering from lupus. The donor of this sum is Miss Dillwyn who has for many years been a member of the Swansea board of guardians and who in 1903 was the means of providing, through an anonymous contributor, a convalescent home with accommodation for 20 patients. This institution was erected at a cost of over £10,000 on the hill-side overlooking Swansea Bay. Nearly 100 patients are sent to it each year from the Swansea Hospital.

Cost of Lunatics.

The average weekly cost of lunatics in county asylums in England and Wales in 1908 was 9*s.* 9½*d.* and in borough asylums 10*s.* 11¾*d.* The charge made to boards of guardians for lunatics in the Glamorgan County Asylum at Bridgend is now 9*s.* 11*d.* per head weekly. An increase of 2½*d.* per head has had to be made owing to the higher price of flour. At the Joint Counties Asylum at Carmarthen the weekly maintenance charge for the past year was 8*s.* 9*d.* per head, and the committee of the Brecon and Radnor Asylum at Talgarth have decided to raise the charge to boards of guardians from 11*s.* 6*d.* per head weekly to 12*s.* 6*d.* This increase is due in large measure to the removal of a large number of Cardiff patients who had been boarded at Talgarth during the building of the Cardiff institution. Their place will now be taken by patients belonging to Swansea, in which town a separate asylum is to be erected. The great cost entailed upon seaport towns in supporting alien lunatics was recently disclosed at Cardiff, where there are some 40 or 50 of this class of patients in the city asylum costing the corporation about £1500 yearly.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Rickets in Glasgow Children.

AN inquiry into the physical condition of Glasgow children admitted to the City of Glasgow Fever Hospital, Belvidere, especially with a view to the incidence of rickets, has been held by Dr. A. S. M. Macgregor, assistant physician at Belvidere and has been published by the medical officer of health. The data tabulated included (*a*) the height of the children; (*b*) the size of the houses from which they came; (*c*) the position of the house in the tenement; and (*d*) the birthplace of the children and also of their parents. Of 1357 children between two and ten years of age rickets was observed among males to the extent of 31 per cent. and amongst females to 26·7 per cent. Of 329 children between six months and two years the incidence among the combined sexes was 42·5 per cent. The rachitic child was found to be of smaller stature than the non-rachitic child at all ages, and in a comparison of the mean heights made with those of the children from the one-, two-, and three-apartment houses, the male rachitic child is uniformly less in height than the non-rachitic child from the one-apartment house, the difference being more notable and amounting to 2 or 3 inches at ages from five to eight years. The female rachitic child was practically the same height (except at the age of six) as the non-rachitic child of the one-apartment house. This fact, along with the lesser incidence of rickets among females, would appear to indicate that females suffer from recognisable rickets less frequently, and show less retardation of growth, than the males. As regards housing accommodation, it is found that the same conditions that affect retardation of growth of the normal child operate powerfully on the susceptibility of the child to rickets. As regards the size of house, it appeared that among male children of the group between two and ten years of age from one-apartment houses 37·8 were rachitic, the figures for two- and three-apartment houses being 29·6 per cent and 12·2 per cent. respectively. For females the corresponding percentages were 34·5 per cent., 26 per cent., and 8·5 per cent. The corresponding figures for the age group between six months and two years are not so striking. It was also noted that in the case of children living in houses of three apartments the number of cases was only 21. It also appeared from Dr. Macgregor's inquiry that the situation of the house in the tenement was almost negligible as a factor in the causation of rickets. An analysis of the parentage of 1277 children was undertaken with a view to determining whether the susceptibility of the child to rickets depended to any extent on its own or its parents' birthplace. It would appear that the percentage incidence of rickets among Glasgow-born children exceeded by 14·4 that among children not born in Glasgow, and by 15·5 that among children who, with their parents, are foreign to Glasgow. It was also found that the mortality among rachitic children from measles or whooping-cough between the ages of six months and two years, was 32·8 per cent., as compared with 21·1 per cent in the case of non-rachitic children.

Death of Dr. A. R. Mackenzie, Fortrose.

The death of Dr. A. R. Mackenzie of Fortrose, which occurred very suddenly on August 4th, has removed a well-known figure in that part of the country. A native of Inverness, he graduated at the University of Glasgow and proceeded to the M.D. in 1851, when he also took the L.R.C.S. at Edinburgh, and thereafter became assistant to the late Dr. Tulloch, Fortrose, on whose death he succeeded to a practice which at that time embraced the whole of the Black Isle. Dr. Mackenzie only retired from practice a few years ago. On his attaining his jubilee as a practitioner he was entertained by the Faculty throughout the north. For many years he was an ardent Volunteer. He also held the positions of medical officer of health for the burgh and parochial medical officer for a very long period. He was a justice of the peace for

Ross and took a lively interest in the affairs of the town, serving for a number of years on the town council. He also occupied the position of chairman of the school board.

Medical Inspection in Fifeshire: Appointment of Medical Officers.

The Fife county joint committee on school medical inspection met recently and appointed four medical officers for the four districts of Fife. For the four male inspectorships there were 23 applicants, who at a previous meeting were reduced to a leet of eight, one of whom subsequently withdrew. The remaining seven appeared before the committee and were afterwards voted upon. Dr. Andrew A. McWhan, Rossville, Cambuslang; Dr. A. F. MacBean, Peterhead; Dr. A. Bremner, Montpelier Park, Edinburgh; and Dr. W. Arnott Dickson, Crosshill, Lochgelly, were appointed. It was left to the medical officer (Dr. T. F. Dewar) to assign the districts to which these gentlemen should be sent, the officer for the Cupar and St. Andrews district to reside in Cupar, for Kirkcaldy in Kirkcaldy, for West Fife and Kinross in Dunfermline, and for Leven either in Kirkcaldy or Leven.

Resignation of the Medical Officer of Health of Ceres.

At a recent meeting of the Ceres parish council notice of motion was given for the next meeting that steps should be taken to dismiss the medical officer of health of the parish, who was fined £25 and severely censured by Sheriff Armour at Cupar recently for entering the parochial shelter at Ceres in the early hours of the morning following Ceres Games and dragging some of the occupants out of bed into the street and assaulting them. The medical officer has now tendered his resignation, and the matter will be considered by the parish council at its next meeting.

Medical Inspection of Schools: Conference at Forres.

The secondary education committee of the county of Elgin was recently asked by the Education Department to formulate a scheme in connexion with the medical inspection of schools, and a conference has now been held at Forres with representatives of the secondary education committee of Nairn and with delegates from the school boards of the county of Elgin. The Forres, Elgin, and Edinkillie representatives said that their school boards did not wish to go into the scheme and were opposed to the medical inspection of schools. Nine-tenths of the children in that part of the country were healthy, and it seemed a ridiculous idea to appoint a medical inspector. After further discussion a delegate moved that they do not go in for the scheme. It was pointed out that this was irrelevant and he ultimately withdrew it. It was then moved that the medical inspection should be carried out either by the local medical practitioners or in conjunction with the county medical officer. It was also moved that the offices be not conjoined, but that an independent medical inspector be appointed, and this was eventually agreed to.

August 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Universities Act.

BY the 20th Section of the Irish Universities Act, 1908, it is enacted that the said Act shall come into operation on such a day, not being more than two years after the passing thereof, as the Lord Lieutenant may appoint. In accordance with this section of the Act, the Lord Lieutenant, in the *Dublin Gazette* of August 6th, appointed the 1st day of October, 1909, as the date on which the Royal University of Ireland is to be dissolved, and on which the two new universities—viz., the National University of Ireland and the Queen's University of Belfast—shall come into being.

The Tuberculosis Campaign.

The Dublin city council on August 10th adopted the compulsory (notification) clauses of the 1908 Tuberculosis Act. It is hoped in Belfast that the Belfast corporation will follow this example of the metropolis The discussion at the recent meeting showed that there was very general agreement among public health experts in favour of compulsory notification of tuberculosis. Meanwhile the war-chest of the tuberculosis campaign has been very materially enriched by Mr. Robert Collier, who has intimated to the Women's National Health Association of Ireland his intention of putting £1000 a year for five years at its disposal, in order that a tuberculosis dispensary may be founded as a memorial of his late father, Mr. P. F. Collier. The announcement of so munificent a gift for the purpose of relief of physical suffering is of special interest at a date when the Dublin corporation has just been discussing the desirability of cutting off its contributions to the upkeep of the city hospitals, with the possible exception of the grants to the Rotunda, Coombe, and Holles Street Maternity Hospitals, and the Cork Street Fever Hospital.

Holiday Home v. Sanatorium at Dalkey.

The discussion of the question of establishing a sanatorium for tuberculous patients at Dalkey has ended happily. Lady Aberdeen received a deputation from the Dalkey urban council last week, and replied to the objections which were raised in the petition which they presented against the project. In replying she expressed the opinion that their views had been formulated "under somewhat of a misconception, as there was not a definite idea of starting a sanatorium," and after some discussion on American precedents she assured her audience that they did not mean to send people in bad stages there—a concession to which Dr. W. McD. A. Wright, the medical officer of health of the Dalkey district, replied that "the only thing that would make the people of Dalkey happy would be to hear that the Irish Women's Health Association had decided not to take a place at all." Her Excellency responded to this expression of view by assuring the speaker that patients will not go there who are in any way consumptive. This reassuring promise was reiterated in a tactful little speech, and the deputation was allowed to take its leave with the full assurance that a recommendation would be conveyed to the executive of the Women's Health Association that if acquired the station would be used as a holiday home for tired workers; and, further, that in that case the institution would be managed by a joint committee on which the Women's National Health Association would invite the urban council to appoint representatives, including the medical officer of health of Dalkey.

Health of Belfast.

The report presented at the meeting of the Belfast city council on August 4th, for the period between June 20th and July 17th, showed that the death-rate from all causes was 13·6, while it was 1·2 from zymotic diseases and 4·1 from chest affections. During this period 70 cases of infectious disease have been notified—viz., 10 of enteric fever, 18 of scarlet fever, 13 of simple continued fever (probably enteric), 4 of puerperal fever, 11 of diphtheria, 13 of erysipelas, and 1 of cerebro-spinal meningitis. There were 35 deaths from zymotic disease, 58 from phthisis, 30 from pneumonia, and 36 from diseases of the respiratory organs (exclusive of pneumonia)—that is, a total of 124 from chest affections.

New Reservoir at Bangor.

On August 9th the water-supply from the new reservoir, which has been constructed at Ballysallagh, in the centre of a beautiful locality about four miles from Bangor, Co. Down, was formally turned on by the chairman of the urban council of Bangor. This new reservoir covers an area of about 30 acres and has a storage capacity of about 75,000,000 gallons, while the total catchment area is 11,000 acres. Taking the population of Bangor at 11,400 and estimating the rate of consumption as 30 gallons per head per day, this gives a water-supply sufficient for 200 days, whilst, in addition, the two reservoirs from which Bangor has up to the present drawn its supply have a storage capacity of 47,000,000 gallons.

The Water-supply of Newry.

At a meeting of the urban council of Newry held on August 9th the surveyor said that at present they were short in their daily supply of water by 200,000 gallons. A complaint was made as to the intermittent character of the supply. The matter is to be investigated.

Electrical Stimulation of the Muscles in the Treatment of Obesity.

SPEAKING at the Academy of Sciences on July 19th M. Bergonié recommended electrical stimulation of the muscles in many of the diseases due to disorders of metabolism. The best forms of electric current for the purpose were those characterised by sudden and regular variations between 40 and 100 times per second. The electrodes were wetted with hot water; they consisted of metallic plates padded with a thick, spongy material and covered almost the whole surface of the body, excluding the face, the front of the chest, the hands, and the feet. The sittings for the application of the current might last for an hour or more without fatiguing the patient, the electrical resistance of whose body might fall below 200 ohms. Under this treatment the respirations were increased and the internal temperature showed an upward tendency. The blood pressure did not rise during this electrically induced exercise; on the contrary, it fell just as in ordinary exercise, and the weight of the fat diminished very rapidly if the food-supply remained at the point of equilibrium existing before the treatment. There was also an improvement in the patient's bodily strength and power of resistance to fatigue.

The Serum Treatment of Rheumatism.

M. Rosenthal, who has been employing the serum treatment of rheumatism in collaboration with M. Thiroloix, described the results at a meeting of the Société de l'Internat held on July 22nd. He found the serum to be not only harmless but prophylactic and curative. Clinically it had a decided effect on generalised acute articular rheumatism but none upon the infectious pseudo-rheumatisms. Its action showed itself both in the affections of the joints, in the visceral complications, in the nervous complications (cerebral rheumatism and rheumatic chorea), and in the renal complications such as albuminuria; it might also reduce the pyrexia. Although sometimes capable of bringing the disease to an abrupt termination the serum generally required to be assisted by medicines, but it appeared in that case to act on the organism somewhat after the fashion of a dyer's mordant, so that patients recovered perfectly under very small doses of pyramidon or antipyrin (in the absence of salicylate of sodium) and after very sparing applications of salicylate of methyl. There was no incompatibility between the serum and salicylate of sodium; the serum of horses immunised against the anaerobic bacterium cultivated from the patient's blood (*hémobioculture*), salicylate of sodium, and colloidal injections were the three essential methods of treating the rheumatic crisis. To prevent relapses M. Rosenthal had prepared with M. Charazin Wetzel a vaccine on Sir A. E Wright's principle—that is to say, an emulsion of bacteria or a cultivation from freshly drawn blood in "physiological serum," and he thought that it was useful to give injections of small doses of this vaccine at long intervals in order to prevent recurrence of the attacks.

The Early Diagnosis of Calculus.

The necessity of the early diagnosis of vesical calculus was insisted on by Dr. Guépin at a meeting of the Academy of Medicine held on July 27th. He said that cases occurred in which very large uric acid calculi (weighing 100 grammes, 180 grammes, and upwards) were overlooked, and he quoted instances observed by himself both in hospital and in private practice. For the relief of such patients who had often been suffering for years it was necessary to perform the laborious operations of lithotomy or lithotrity, the results of which were not always quite satisfactory, whereas early diagnosis would have enabled the condition to be dealt with by a short operation offering a good prospect of success. Even when a vesical calculus was very large the symptoms might be very obscure, so that in all doubtful cases it was necessary to examine the bladder carefully; the best method of doing this was undoubtedly the one brought into notice by M. Reliquet, the well-known inventor of the instruments employed at the present time for crushing calculi. Proceeding in this way an operator of the requisite experience would recognise even the smallest calculi and appropriate treatment could then be undertaken.

Occlusion of the Intestine by an Intraperitoneal Band.

A case of occlusion of the intestine by an intraperitoneal band was described by M. Potherat at a meeting of the Surgical Society held on July 28th. The patient was a man, aged 21 years, who after completing his military service in Tunis returned to France, where he had an attack of malaria and afterwards suffered from lead poisoning attributable to his occupation as a plumber. He was then treated for abdominal symptoms which were regarded as due to appendicitis, and on an operation for the removal of his appendix being performed in 1907 it was found to be large and ecchymosed. In a few weeks he returned to his employment. In December, 1908, he presented symptoms of intestinal obstruction for which laparotomy was performed but no lesion was discovered. The stoppage of the bowels was relieved to some extent but afterwards became urgent and was accompanied by vomiting. Entering the Hôpital Broussais he was seen by M. Gilbert who was not disposed to accept the diagnosis of lead poisoning. After some days the fæces became dark-coloured and were blood-stained and flatus was passed with difficulty. The diagnosis of tuberculous enteritis was suggested but the examination of the fæces was negative. The symptoms of chronic obstruction at length became acute and were accompanied by fæcal vomiting; laparotomy was then performed with the result that some coils of intestine which were found to be adherent to the abdominal wall were separated without difficulty. Amid these coils there were a pouch from which serous fluid escaped, and underneath it there was a coil of intestine of an absolutely black colour with an adherent band encircling both it and the mesentery. This band had probably caused the congestion of the intestine and the subsequent hæmorrhage; the diameter of the intestine was also diminished. After division of the band the patient made an uneventful recovery.

The Reduction of Infantile Mortality in New York.

Mr. Robert Simon, who has for four months been conducting inquiries in New York with reference to the infantile mortality in that city, made a communication on the subject at a meeting of the Academy of Medicine held on July 20th. He said that during the period from 1898 to 1908 the infantile mortality in New York diminished by one-third—namely, from 214 per 1000 to 144 per 1000. This result was due in great part to the efforts of a private association for improving the condition of the lower classes and to the pressure which it exercised on the official sanitary services. Among the methods followed by the association, some of which might be found useful in France, Mr. Simon mentioned in the first place the arrangements that were made in summer time for the protection of young infants from the intensely hot atmosphere of urban dwellings by removing them and their mothers to open-air camps, seaside hospitals, and floating hospitals. These institutions were also of great service in teaching mothers the proper way of bringing up children. Another noteworthy point was the supply of milk guaranteed by a certificate issued under the supervision of the municipal laboratories. This certificate was only issued from day to day (*délivré chaque jour et révocable de même*) and required compliance with the following conditions: the milk must come from cows that have been tested with tuberculin; it must not contain more than 30,000 bacteria per cubic centimetre (in Paris there may be 5,000,000 bacteria per cubic centimetre at the end of 24 hours); it must be sent out in sealed bottles kept in ice; and it must be sold at the latest 36 hours after milking. These bottles must be filled and sealed at the farm and not in New York; they must also show the name of the farm and the day and hour of milking. Milk sold under this guarantee was, as might be expected, recommended for general use. Specially trained nurses made frequent visits to families in which there were very young infants, and they also kept regular observation upon pregnant women of the poorer class. Among infants born of poor parents and not brought under the notice of the visiting nurses until the day after birth the mortality was 17·1 per cent., but it fell to 4·7 per cent. when the mothers have received attention from the nurses for a period of a month or more previous to the termination of their pregnancy. A nurse visits 100 mothers annually and Mr. Simon considers that during that time she saves the lives of 12 children who in ordinary circumstances would have died.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

What did the late Pope Die from?

"SENILE decay" was the accepted answer, and considering that he closed an eminently studious and strenuously active [illegible] death to have been tuberculosis. This disease, he maintained at a recent conference, may continue latent in the system, and then, at a given moment, "manifestarsi nel massimo vigore anche nell' età più tarda" (show itself in great force even at the most advanced age). Of this, he says, the late Pope was a typical example, succumbing as he did to "an acute attack of latent tuberculosis," when within little more than five years of being a centenarian.

The Italian Delegation at the Sixteenth International Congress of Medicine at Budapest.

At the conference above referred to Dr. Baccelli announced that he had just been honoured by Government with the task of organising a commission of delegates to represent Italy at the Sixteenth International Congress of Medicine which is to meet at Budapest on August 29th. On that commission, of which he is to be president, there will serve some Italian physicians whose studies have recently been directed to tuberculosis—a subject, moreover, to which the attention [illegible] "There is no [illegible]" (continued [illegible] 'tubercolo' [illegible] through that channel. Had it been possible by that route to attack it I would have done so when, having recourse to heroic remedies, I opened the veins. For syphilis—to say nothing of the cerebro-spinal bacteria—I have satisfied myself of the truly marvellous effects of the intravenous injection of the sublimate, by which I got 'on terms' with the 'granulazione.' Those who hold that tuberculosis is summed up in the bacillus of Koch are, I maintain, quite in error. I still adhere to the opinion formed years ago when Koch's discovery was made *publici juris*, and his 'tuberculin' was introduced into practice—namely, that the bacillus in question is only 'l'esponente microscopico dei tubercoli' (the microscopic exponent of tubercle), being by no means co-extensive with tuberculosis, still less with phthisis.

Padua: the Seat of the Italian Association for the Advancement of Science.

On the lines of its British counterpart, the third meeting of the Italian Association for the Advancement of Science will be held at the great Venetian seat of learning—the first having met at Parma in 1907 and the second at Florence. The sittings will extend from Sept. 22nd to 26th, and the programme, to which the finishing touches are now being put, will be one of exceptional interest. It is in nature-study, physics, and the medical sciences that Italy is giving most decisive proof of the resuscitation of her genius, and the organising committee of the association teems with names of distinction in all these studies—particularly the medical. I need only mention those of Golgi, Grassi, and Sanfelice to indicate the representative character of medicine. The two last named will take a prominent part under the Biological Section, while Golgi will give further illustrations of the discoveries with which he has already enriched neurology. Pigorini in palæontology and Grocco (following up last year's exposition by the Senator Colombo) will make still fresher contributions to the theme now on everybody's lips—that of aerial navigation. The opening address will be delivered by that master in academic oratory, Professor Luigi Luzzatti, who holds the chair of Constitutional Law in the University of Rome, his special thesis being the progress recently made by Italy in science and how that progress may [illegible] ted as she is with the early [illegible] anatomy, and in medicine—prominent among whom stands out for all time the name of William Harvey.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Venomous Snakes in Austria.

IN the southern part of the empire there are several kinds of venomous snakes and the Government endeavours to prevent their increase by paying a small reward for each snake killed. In 1907 no fewer than 280,718 snakes were thus destroyed, 271,685 of them being venomous and mostly vipers. In 1908 the number fell to 273,500 snakes captured, of which 269,531 belonged to venomous kinds. In 1907 there were 206 persons bitten by these pests, with 18 fatal results. The increased knowledge of the habits of the snakes, together with the precautions that have been taken, lowered the number of persons bitten last year to 140, of whom six died. In accordance with a suggestion made by Professor Riehl, the inhabitants of the infested districts have been furnished with a small appliance, consisting of a knife for the immediate enlargement of the wound inflicted by a snake, and in the handle of this knife there is a supply of small tablets of permanganate of potassium, to be used immediately on the receipt of the wound, as it has been discovered that the venom may be destroyed by a concentrated solution of the above substance. This precaution has proved very satisfactory in the hands of the local peasantry.

Death of Professor von Vogl.

The Austrian medical profession has sustained a severe loss by the death of Professor Augustus von Vogl, Imperial councillor and emeritus professor of pharmacology and materia medica. The deceased was well known to many generations of medical men, as from 1874 to 1904 he both [illegible] the M.D. degree after the introduction of the modern curriculum for medical students in 1860. His industry and wide intelligence soon raised him above the level of his contemporaries and 10 years later he became professor of pharmacology. His chief merit was the introduction of modern methods of scientific research into his branch of medicine, making use of the comparatively new sciences of histology and microscopy for investigating the nature of the officinal plants; experimental pharmacology was also first cultivated by him in this country. Many foreigners came to Vienna for the purpose of attending his lectures in 1874 onwards. On account of his important contributions to the advancement of his specialty he was awarded the Hanbury medal, together with many other foreign distinctions, and he saw his text-book on materia medica translated into almost all the civilised languages. The principal published works of Professor von Vogl are the text-book above mentioned, the "*Anatomical Atlas of Pharmacological Plants*," and the "Methods of Detection of Adulteration of Food" He also founded the "Codex Alimentarius Austriacus," in which the chapters on flour, mushrooms, fruit, and condiments were all his own work. Professor von Vogl was elected rector magnificus of the University of Vienna in 1888, and ten years later he was appointed Oberste Sanitatsrath, or president of the chief board of health in Austria. In this position he endeavoured to introduce the principles of modern hygiene in all cases where the Government had a right to interfere, and many useful orders and regulations with respect to the sale of articles of food and other points of public health were due to his efforts. He was highly esteemed by his colleagues. His students found in him a strict but just and kindly examiner of whom they did not stand in awe, and when, a short time before vacating his chair, he received a title from the Emperor the distinction was deemed an honour to the profession. For the last four years he lived in retirement, having reached his seventieth year in 1904

Dental Surgeons and Dental Mechanics.

The conflict between the dental surgeons and the dental mechanics has lately assumed the character of a battle in which qualified and unqualified practitioners are struggling for supremacy and it therefore deserves the careful attention of the entire medical profession. In this country the practice of dentistry is restricted to the dental surgeons who must possess an M D. degree and must have also passed certain dental examinations. The progress of artificial dentistry, especially the art of crown-bridge work and regulation of the teeth, has brought into existence a large number of assistants to the dental surgeons, men without any medical degree or systematic instruction but possessing a good knowledge of the mechanical processes employed in artificial dentistry. Ever since dentistry became a lucrative occupation these men have tried to become independent of the surgeons and have encroached upon the domain of the latter until they undertook extraction of teeth, filling of cavities, and other surgical procedures without interference from the governmental authorities or medical corporations. Growing bold by degrees they have been endeavouring to have the practice of dentistry freed from the existing restrictions and thrown open to all who belong to the "guild" of dentists. The dental surgeons have naturally taken active steps in defence of their rights; and in the vicissitudes of this strife the governmental decisions have been partly for and partly against the medical men. At last a compromise was suggested by the unqualified dentists—namely, (1) that dentistry should in future be practised only by men holding the degree of M.D., and that no new dentists should be admitted to the "guild," so that this class would in course of time die out, leaving the field to the qualified men; and (2) that the dental mechanics should meanwhile be entitled to do all work necessary for the fitting of artificial teeth in the mouth. As this second condition meant nothing else but a tacit permission that surgical work might be done by men not having any hospital experience or medical diplomas the compromise was not accepted by the dental surgeons. Having obtained the help of some Members of Parliament the dental mechanics now began to demand a complete separation of the two branches of dental practice; the purely surgical one (filling of cavities and extraction of teeth) they offered to leave to the dental surgeons, whilst for themselves they asked for nothing else but the purely mechanical branch (artificial dentures, crowns, bridges, and regulation of teeth), together with permission to carry out the minor surgical procedures in the mouth necessary to fit in the dentures, such as the extraction of stumps, preparation of teeth for crowning, &c. This would mean, on the one hand, the absolute ruin of the dental surgeons and, on the other hand, the legalising of surgical practice on a special part of the human body by unqualified men. The whole profession has been roused and a meeting, arranged by all the medical corporations, has taken place in Vienna for the purpose of making a protest. All the speakers in this meeting pointed out the dangers threatening the public from the indiscriminate granting of permission to practise dentistry. As the dental mechanics have brought many influential men over to their side it is not impossible that they may be successful in their endeavours. Concerted opposition by the entire profession must therefore be organised, the public must be informed of the actual facts through the press, and there is still hope that victory may remain with the profession.

August 9th.

CHINA.

(FROM OUR OWN CORRESPONDENT.)

Shanghai Health Report for 1908.

THE carefully kept returns of Shanghai are valuable as being indicative—to a good extent as far as Europeans are concerned—of the health conditions of other treaty ports in China (i.e., ports open to foreign trade). The report just issued declares the public health during 1908 as satisfactory, with no exceptional incidence of any preventable disease. The group of bowel diseases—typhoid fever, cholera, dysentery, sprue, &c.—to which the non-Asiatic resident in the Far East is peculiarly susceptible, and which may be avoided by the use of sterilised food, have been less prevalent. The degree of prevalence of this group of maladies is perhaps the best index of sanitary education as locally acquired. Tuberculosis is still rife, and because of its commonness there is a tendency to consider it a necessary evil. Over 1000 Chinese die from this disease yearly in Shanghai, and this enormous death-rate will continue, irrespective of climate, as long as there is no legislation to prevent indiscriminate spitting and overcrowding with deficient air space. Small-pox of mild type was prevalent to a small extent during the first quarter of the year. The conscientious objector to vaccination has no troubles in China, the powers that be leaving this matter entirely to the people to take it or leave it, as they may choose. It is therefore noteworthy that during this year 4649 vaccinations have been done at the Health Office, as compared with 465, 380, 520, and 1418 of previous years, and it seems probable the Chinese will take up vaccination widely. As Dr. A. Stanley says, "small-pox should soon be looked upon as a mediæval scourge, only surviving in countries imperfectly civilised." Only two deaths were certified as due to Malta fever, and although 37 specimens were examined in the laboratory, in none was the diagnosis confirmed. A few cases of cholera were notified during the summer, but again the diagnoses were not confirmed in the laboratory. Following the dictum of "No rats, no plague" as a working basis, most energetic methods of rat destruction have been carried out, but it has been found that these measures are ineffectual in reducing the rat population—their reproduction easily keeping pace with their destruction—unless combined with active steps to make houses as rat-proof and therefore as plague-proof as possible. Solid basements, removal of stair linings, hollow ceilings, and hollow partitions, are required of house owners in the notices which are served to them. No doubt these and other similar activities on the part of the public health department have not been without good effect. At the same time the immunity of Shanghai to plague is a most remarkable fact, when one considers that, since its introduction to the Far East in 1894, plague has been epidemic in North, Mid, and South China, and until last year the only restrictions imposed by the port health authority on ships arriving in Shanghai were directed against human cases and not against rats, now recognised as the chief disseminators of plague between port and port. This problem is the more difficult to solve when one considers, again to quote Dr. Stanley, that "Shanghai is a rat-infested community, that there is no legislation whatever against overcrowding, that isolation of infectious diseases cannot be enforced, that the great mass of the population is an alien one, mostly ignorant of the rudiments of sanitation, and that there is an almost entire absence among the Chinese of the responsibilities of citizenship as understood in communities educated according to modern standards." A constant unrestricted shipping trade is kept up with Bombay, Hong-Kong, and other endemic centres; the temperature is favourable and, as noted in previous letters, plague was found to be existent among the rats, though in a small proportion; it is therefore seen that here are all the elements favourable to an outbreak. One is tempted to doubt the generally accepted theory of the rat and its fleas being the sole means of epidemic spread and to look for other causes. At Shanghai there is efficient port health examination, and up to the present no cases of human plague have been allowed to land. The spread from man to man is thus interfered with so far as pneumonic plague is concerned. Any increase in the number of sick or dead rats would soon be detected by the sanitary staff. There, however, remains a break in the chain of circumstances necessary for human infection which has not been satisfactorily explained as yet.

The Murder of Dr. C. Lalcaca.

Dr. Lalcaca was one of the best known and most prominent medical men in Shanghai, where he had practised for 23 years. You are certain to have given particulars of his career.[1] In Shanghai he was one of the leaders of the local Parsee community. He was very popular socially and was one of the keenest members of the Shanghai Volunteer Corps, in which he held the rank of surgeon-major and principal medical officer of the corps. All matters affecting the Parsees possessed warm interest for Dr. Lalcaca, and it was always felt that although he came most frequently into association with people of other foreign communities his own people were never forgotten and ever retained a place in his affection. Not only residents in Shanghai, but people of the Far East generally, from Japan to India, are mourning the tragic termination to an active, useful, and unselfish life.

The Far Eastern Association of Tropical Medicine.

This society has been formed as the outcome of a report made by a committee appointed by the Philippine Islands

---

[1] THE LANCET, July 10th, 1909, p. 120.

Medical Association. It is hoped thus to unite into one compact organisation the medical profession in the Far East. In addition to promoting the science and art of tropical medicine it, among other objects, hopes to advance and elevate the standard of medical education among Asiatics. The first biennial meeting will be held in March, 1910, at Bagnio, Benguet, the summer capital of the Philippines, and a programme in outline is now being circulated calling for papers on protozoology, helminthology, dysentery, beri-beri, cholera, plague, leprosy, &c. There will be a day specially devoted to tuberculosis. A visit to the Philippines, with the opportunity for inspection of the progressive methods of the American Naval and Military Services and of meeting American medical men, should be a strong incentive to make this first meeting a success. Dr. Francis W. Clark, medical officer of health of Hong-Kong, is the secretary-treasurer for China.

July 10th.

Obituary.

ARTHUR FOXWELL, M.D. CAMB., F.R.C.P. LOND.,

PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM; PROFESSOR OF THERAPEUTICS, UNIVERSITY OF BIRMINGHAM.

BY the death of Dr. Arthur Foxwell, senior physician to the Queen's Hospital, Birmingham, under exceptionally sudden and sad circumstances, the medical profession has suffered a great loss. Dr. Foxwell was riding a bicycle near Warwick on the evening of Sunday, August 1st. While descending a hill a dog ran out suddenly into the front wheel of the machine. Dr. Foxwell was thrown violently over the handle-bar, was picked up insensible, and was removed at once to the Warneford Hospital, Leamington. It was found that he had sustained severe injuries to the head and spine from which he never regained consciousness and from which he died on the early morning of Wednesday, the 4th.

Dr. Foxwell was born at Shepton Mallet on July 13th, 1853; he was the third son of the late Mr. Thomas Somerton Foxwell of Weston-super-Mare. He received his early education at Queen's College, Taunton, afterwards at St. [illegible] College, Cambridge, and subsequently at St. Thomas's [illegible] Lond. with honours in [illegible] in 1877, also with honours in natural science, in 1883 the degree of M.B. (first class in medicine), and in 1891 the degrees of M.A. and M.D. He became a Fellow of the Royal College of Physicians of London in 1892, and received the degree of M.Sc. of Birmingham on his appointment as Professor of Therapeutics in that University in 1901. After holding the posts of house physician to St Thomas's Hospital, clinical assistant to the Brompton Hospital, and medical officer to the Children's Hospital, Pendlebury, he was elected to the office of pathologist to the General Hospital, Birmingham. From this he was appointed assistant physician during the years 1885 to 1889, when he was elected to the staff of the Queen's Hospital, which post he held to the time of his death. He was Bradshawe lecturer of the Royal College of Physicians of London in 1899, gave the Ingleby lectures in Birmingham in 1892, was examiner in medicine at the University of Cambridge, and also held a number of other pro- [illegible] Foxwell filled a place in the [illegible] that was due wholly to his [illegible] head and heart, and because [illegible] ill that place which he has left so suddenly in the fulness of his powers, and when his wide experience was yielding a rich return for years of patient and accurate work.

It is not an easy task to single out for remark any quality in one whose whole personality was strongly marked. But whatever the circumstances, whether as the hospital physician, the teacher, the doctor, or the man in his own home, the feature which attracted above all others was his high ideal of life and work. Work was to be done for its own sake, and work well done never failed to meet with generous appreciation and honour from him He himself was a worker of the first order, with a gift of keen criticism. No new idea or f [illegible] was accepted without a t[illegible] imself, for so deep was hi[illegible] detected any flaw in argument and any misinterpretation of facts. His clinical teaching, therefore, was of a high standard, more adapted perhaps for the senior student than the junior, in that his extensive knowledge of pathology and higher medicine took him so far ahead that at times he seemed to forget that it was not given to all his students to follow where he led. Dr. Foxwell appeared at his best and often in his brightest moods at consultations of the hospital staff; then he gave free rein to his faculty for drawing inferences from observed facts. It was on these occasions that his power of criticism was keenest, and when it happened that the case down for discussion was his own, his summing up of evidence for a diagnosis was a lesson in clinical medicine. A similar accuracy in the observation of facts and care in drawing conclusions characterised all his writings, and none could speak or write with greater ease or grace, for in all his teaching and writing he was fastidious. His contributions to medical literature are select. His investigations into the causation of functional defects of the heart, the pericardium, vascular diseases, and lesions of the liver are well known and have set a standard of clinical research in Birmingham among his colleagues. He published the following works: In 1895, "Essays in Heart and Lung Disease"; in 1896, "The Enlarged Cirrhotic Liver"; in 1897, "The Spas of Mid-Wales"; in 1899, "The Causation of Functional Heart Murmurs," the Bradshawe Lecture which appeared in THE LANCET, as did his address on "Inhalation" in 1907, and on "The Clinical Examination of the Urine with Especial Reference to the Estimation of Urea" in 1908. He published a number of papers in other medical journals. He strongly believed in the climatic treatment of disease, and to this subject he devoted a great deal of attention. He had travelled much to visit the health resorts of Switzerland, France, and Germany, and his lectures on climatology were largely the result of personal knowledge of the places where patients are usually sent

Dr. Foxwell held strong views as to the duties of members of the staff in addition to their clinical work in the hospital. He took a great interest in the building of the new medical block at Queen's Hospital and his speech at the opening ceremony in 1908 is well remembered by those who were present for its aptness and grace of diction. To Dr. Foxwell was due the construction of a roof ward in the medical block, for so fully did he realise the advantages to be gained by treating acute diseases of many kinds in the open air that his strong advocacy prevailed and an important and new feature was introduced into the routine of hospital treatment. Already results have shown the wisdom of his advice. In point of fact, the general design and arrangement of the medical block are due to this wise physician's versatility, as the plans were largely drafted on his suggestions.

Dr. Foxwell's share in public work did not extend much beyond Queen's Hospital. He was not physically strong, and although he took a constant interest, and held office, in the medical societies, he felt constrained to spare his energy. For this reason he did not appear in municipal life, nor even much in society, though he held strong opinions on, and watched with interest, all that concerned the welfare of the community. As in his work, so in his private life his ideal was high and his interests many and varied. He had a great love for his garden, and his beautiful home—Northfield Grange—was typical of his refined tastes. Those who were privileged to see him there were always conscious of a peculiar influence, almost a fascination, he had over others, due to a wide culture. He talked with an ease on literature, art, and nature that could only come of acquaintance grounded on thoughtful appreciation of those things which make for fulness of life. Like many of high intellectual order, he had several sides to his character—the cold, clear, and logical, and the contemplative, almost mystical. In movements of expansiveness—for in many ways he was a reserved man—he would talk with keen delight of the simple everyday joys of life, and pass thence to speak of what he called the "dreamy West Country," from which he came. His friends knew that he was loyal and true; that his advice was at their service in all matters where help was needed. It has already been suggested to found a prize or medal in his memory, to be given for proficiency in clinical research or some branch of medicine in which he was particularly interested.

Dr. Foxwell married in 1880 the widow of the late [illegible] Robert Pollack, and daughter of [illegible] Mr. [illegible] much needed improvement; and Mrs. Bedford Fenwick called attention to the need of reform in our own naval nursing service, which had not profited, like the army nursing, from the South African war. The last day's conference was concerned with health and mission nursing in foreign fields.

THE ROYAL UNITED HOSPITAL, BATH.—A new out-patient department, an isolation house, and a home for the accommodation of the nursing staff have been recently added to the Royal United Hospital, Bath.

Dr. Hansen of Bergen and Dr. Morisani of Naplés have been elected Foreign Associates of the Paris Academy of Medicine.

A DEVONSHIRE CENTENARIAN.—Mrs. Johanna Dillon of Inwardleigh, who celebrated the 103rd anniversary of her birthday on June 26th, died on July 31st. She was born at Coleridge, Devon, and had always resided in her native county.

EAST CORNWALL HOSPITAL, BODMIN.—The committee has decided to erect a new hospital in Rhind-street, Bodmin. Plans have been approved and the new building will contain male and female wards to accommodate six beds each, two private wards, operating theatre, out-patient department, consisting of consulting-room, dispensary, &c., accommodation for the matron and medical staff, &c.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Anæsthetics Bill.

SIX notices of motion to reject Mr. COOPER'S Anæsthetics Bill now stand on the order paper of the House of Commons. The Members who have brought forward those notices are Mr. SNOWDEN, Mr. WILES, Mr. HARWOOD, Mr. JOYNSON-HICKS, Mr. HOGAN, and Mr. KENDAL O'BRIEN. With opposition in front of it, there is no chance of further progress being made with the Bill at this period of the session.

Ambulances (Metropolis) Bill.

Mr. PEEL'S Ambulances (Metropolis) Bill, which is now published, provides that the ambulance service in the metropolis should be maintained by the Metropolitan Asylums Board. This carries out the recommendation of the majority of the recent Departmental Committee in regard to the authority which is to administer an ambulance service in London. Two members of the committee favoured this plan, but the third, Sir WILLIAM COLLINS, M P., desired that the work should be undertaken under the auspices of the County Council. Soon after the issue of the report of the Departmental Committee he introduced into the House of Commons his Metropolitan Ambulances Bill, making the County Council the administrative authority. A second reading has been obtained for it, and it is now awaiting consideration at the hands of a Parliamentary Committee. The outlines of this situation are set out in a memorandum to Mr. PEEL'S Bill, and it emphasises the fact that his measure follows the recommendation of the majority of the Departmental Committee. Besides proposing the Metropolitan Asylums Board as the authority to establish the ambulance service, it also provides, in accordance with the report of the committee, that the Commissioner of Police of the metropolis should be empowered to enter into agreements in connexion with such a service (1) with the Metropolitan Asylums Board; and (2) with the board of guardians of the poor of any parish or union without the county of London but within the metropolitan police district as to the use of ambulances for street cases in that district. It is also stated in the Memorandum that on June 3rd, 1909, the Secretary of State for the Home Department asked to be furnished with the observations of the Metropolitan Asylums Board on the report of the departmental committee, and on June 19th, 1909, the Board passed the following resolution:—

"That the Secretary of State for the Home Department be informed, in reply to his letter of the 3rd June, 1909, that the managers entirely concur in the evidence given by the clerk to the Board before the Departmental Committee on the Ambulance Service in the metropolis; and that in the event of the necessary authority being conferred on the managers by Parliament, they are convinced that they could speedily and economically inaugurate an efficient service of rapid ambulances for 'street cases' for the administrative county of London, and, if considered desirable, for the outlying portions of the Metropolitan Police District."

Lord ROBERT CECIL, Mr. CROOKS, Mr. HENRY GOOCH, and Mr. HAY were associated with Mr. PEEL in bringing forward the Bill.

Local Education Authorities (Medical Treatment) Bill.

When the House of Lords on Wednesday, August 4th, considered the Local Education Authorities (Medical Treatment) Bill in committee Lord BELPER expressed a fear that one of its clauses, if unaltered, would introduce an optional element into the medical inspection of school children under the Act of 1907. The Earl of CREWE promised to investigate the matter before the next stage of the Bill, which was then allowed to pass through committee without amendment.

Milk Legislation and Tuberculous Cows.

An obstacle to the rapid passage of the Bills dealing with milk-supply and dairies in England and Scotland was disclosed in a short debate in the House of Lords on Wednesday, August 4th. For their full effect these measures are, in great degree, bound up with the Tuberculosis Order recently issued by the Board of Agriculture. Under it compensation is proposed to be given for cattle slaughtered on account of tuberculosis. On August 4th the Government were pressed to give an estimate of the probable cost of compensation so far as Scotland was concerned. Lord PENTLAND, the Secretary for Scotland, replied that at present the Board of Agriculture had no reliable statistics on which to form an estimate, but the President of the Board was engaged in an attempt to arrive at a computation of the number of cattle which would fall to be dealt with under the tuberculosis order. He further demurred at the suggestion that the progress of legislation should be hung up pending the result of the inquiries of the Board of Agriculture. This evidently was not the view of several other noble lords. They urged the advisability of waiting for the statistics to be provided by the Board of Agriculture before giving the Bill a third reading. Some objection was also taken to the course adopted by the Government of dealing with England and Scotland in separate Bills. The result of the discussion was that the Earl of CREWE, on behalf of the Government, with unconcealed reluctance, agreed to defer the motion for the third reading of the Milk and Dairies (Scotland) Bill. Some of the considerations advanced in favour of the delay of this measure would apply with equal force to the case of the English Bill. The session is now far advanced, and as the main attention of Parliament will be devoted to the controversies involved in the Finance Bill, the prospect of the Government's Milk Bills reaching the Statute Book this year is becoming less and less assured as the weeks pass.

The Parliamentary Session.

For a fortnight there has been a lull in the proceedings of the House of Commons. Many honourable Members have been taking a holiday, but with the reappearance of the Finance Bill this week, as the principal order of the day, the strenuous life of Parliament has recommenced. This is the season of the year when Governments are usually trying to wind up the session with expedition. However, this year it would seem that the hardest weeks have yet to come. There is a prospect of many prolonged sittings extending into the morning hours, and bringing with them a great strain on the physical resources of Members who remain in attendance at Westminster.

The Report of the Whisky Commission.

In the Final Report of the Royal Commission on Whisky and other Potable Spirits the Commissioners are unable to recommend that the use of the word "whisky" should be restricted to spirit manufactured by the pot-still process, stating that they have received no evidence to show that the form of still has any necessary relation to the wholesomeness of the spirit produced. They have framed a definition of "whisky" to which the product of both the pot and patent still processes may conform. According to it whisky is a spirit obtained by distillation from a mash of cereal grains saccharified by the diastase of malt. The Commission devoted a considerable portion of its inquiries to brandy, rum, geneva, gin, and liqueurs. One of the conclusions come to is that the term "brandy" is applicable to a potable spirit manufactured from fermented grape-juice and from no other materials. However, it is added that the compounded spirit recognised by the name of "British brandy" is entitled still to be sold under that designation. The report is a unanimous one.

HOUSE OF COMMONS.

THURSDAY, AUGUST 5TH.

Civil Surgeons in India.

Mr. J. MACVEAGH asked the Under Secretary of State for India whether he was aware that the civil surgeons in India were usually medical men belonging to the Indian Medical Service, and that their duties were very light and left them ample time for private practice; whether the same work was done in the native states by medical men who did not belong to the Indian Medical Service at a much less cost and to the entire satisfaction of the Government and the public; and whether he could say when he woul[illegible] proposed scheme for the reform of the medical service of [illegible] ELIBANK wrote in reply: The hon. Member is [illegible] the civil surgeons in India are usually officers [illegible] Service. The Secretary of State has no detailed information as to the amount of time which they are able to spare from their official duties for private practice, nor is anything known as to the work of medical practitioners in native States. The Secretary of State is still in communication with the Government of India in regard to the best means of promoting the growth of an independent medical profession in India.

Plague in India

The MA[illegible] State for India, in the course of [illegible] aid that with regard to plague, it [illegible] last two years was encouraging [illegible] it was hoped that the worst had been seen of the disease In each of the two preceding years the mortality had exceeded 1 000,000, but in 1906 it dropped to 357,000, and keen was the [illegible] following year [illegible] ortality of up- [illegible] its strength [illegible] that of the [illegible] onths of this [illegible] s the mortality was always [illegible]

[illegible] should be combated and were show [illegible] coöperate with the Government in [illegible] scientific aspect. The Government [illegible] responsibilities and attached so mu [illegible] knowledge that simple instruction o [illegible] schools of the land [illegible] leman expressed apprecia [illegible], Dr Lalcaca, who gave his [illegible] Sir Curzon Wyllie.

TUESDAY, AUGUST 10TH.

The Heroism of Dr Lalcaca

Mr KEIR HARDIE asked the Under Secretary of State for India [illegible] action, and I can only repeat that it shares in the fullest degree the [illegible]

Reported Cholera at Calcutta.

Mr. REES asked the Under Secretary of State for India whether the Government of Bengal had instituted inquiries into the ten deaths reported of cholera in the Presidency European Hospital, Calcutta, whether it had determined whether the deaths were due to cholera, [illegible]

WEDNESDAY, AUGUST 11TH.

Royal Army Medical Corps

Mr. ASHLEY asked the Secretary of State for War what was the [illegible]

BOOKS, ETC., RECEIVED.

APPLETON AND CO, London.

The Principles and Practice of Medicine By William Osler, M D, F R S, F R C P Lond, Regius Professor of Medicine, Oxford University. Seventh edition, thoroughly revised. Price, cloth, 21*s* net.

ASSELIN ET HOUZEAU, Paris.

Les Maladies des Enfants [illegible] de MM Babonneix, Bige [illegible] Lesne, G Leven, Louis [illegible] L Tixier, Vitry, Roger V [illegible]

Modern Problems in Psychiatry. By Ernesto Lugaro. Translated by David Orr, M.D., and R. G. Rows, M.D. With a Foreword by T. S. Clouston, M.D., LL.D. Price 7*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

HILL, WALTER JAMES, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health of Clevedon, Somerset.

IRELAND, ARCHIBALD EDWARD, M.R.C.S., L.R.C.P. Lond., D.P.H. Oxon., has been appointed Medical Officer of Health and Government Bacteriologist, Suva, Fiji.

LLOYD, BRIMLEY R., M.B., B.S. Lond., D.P.H., has been appointed Medical Inspector of Schools at Sheffield.

NASH, E. H. T., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health of Wimbledon.

RUSSELL, R. F., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ollaberry District of the county of Zetland.

TRIMBLE, ROBERT, M.D. Glasg., has been appointed one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 4, and to be attached more particularly to Preston, Garstang, and Chorley County Courts.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM UNIVERSITY (FACULTY OF MEDICINE).—Professorship of Anatomy. Stipend £800 per annum.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRISTOL, BRENTRY CERTIFIED INEBRIATE REFORMATORY, Westbury-on-Trym.—Superintendent and Medical Officer. Salary £400 per annum, with board and residence.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

CAMBRIDGE UNIVERSITY, PATHOLOGICAL LABORATORY.—John Lucas Walker Studentship. Value £200.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £70 per annum, with board and lodging.

CAPETOWN, SOMERSET HOSPITAL.—Assistant Surgeon. Salary £200 per annum, with rations and quarters.

CHELTENHAM GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board and lodging.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Honorary Ophthalmic Surgeon.

COLCHESTER, ESSEX COUNTY HOSPITAL.—Honorary Dental Surgeon.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

EBBW VALE STEEL, IRON, AND COAL CO., LIMITED.—Medical Officer for the Inspection of Injured Workmen. Salary £250 per annum.

ECCLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £60 per annum, with board and washing.

EDINBURGH DISTRICT ASYLUM, Bangour Village.—Third Assistant Medical Officer and Pathologist (female). Salary £120 per annum, with board, apartments, and laundry.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—Two Clinical Assistants in the Ear and Throat Department.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Two Clinical Assistants in the Out-patient Department for four months. Salary at rate of £100 per annum.

JAFFRAY BRANCH OF THE GENERAL HOSPITAL, Gravelly Hill, near *Birmingham.—Resident Medical and Surgical Officer Salary £150* per annum, with board, residence, and washing.

LANARK, COUNTY OF.—Two Medical Officers for the Examination and Supervision of School Children. Salary £350 per annum, with travelling expenses.

LEEDS INFECTIOUS DISEASES HOSPITALS.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing.

LEICESTER INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, apartments, and washing.

LEIGH, BOROUGH OF.—Medical Officer of Health. Salary £400 per annum.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Physicians and Three House Surgeons. Salary at rate of £60 per annum, with board and residence.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Resident Medical Officer. Salary £120 per annum, with board and residence. Also Assistant Resident Medical Officer for six months. Salary at rate of 50 guineas per annum, with board and residence.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £80 per annum, with apartments and board.

MILE END OLD TOWN INFIRMARY AND WORKHOUSE, Bancroft-road, E.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer at Hampstead, also Assistant Resident Medical Officer at Northwood. Salary in each case £50 per annum, with board and residence.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NORWICH, HEIGHAM HALL PRIVATE ASYLUM.—Assistant Medical Officer. Salary £120 per annum, with all found.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—House Physician, unmarried. Salary £80 per annum, with board, lodging, and washing.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, with apartments, attendance, light, and fuel.

PUBLIC DISPENSARY, 122, Drury-lane, W.C.—Resident Medical Officer. Salary £105 per annum, with apartments

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and lodging.

SOUTHWARK INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

STOKE-UPON-TRENT WORKHOUSE.—Resident Medical Officer. Salary £175 per annum, with board, washing, and apartments.

SUNDERLAND AND DURHAM COUNTY EYE INFIRMARY, Sunderland.—House Surgeon, unmarried. Salary £210 per annum.

SUNDERLAND, MONKWEARMOUTH AND SOUTHWICK HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician, also House Surgeon for six months. Board, lodging, and laundry provided.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with board and lodging.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, lodging, and laundry.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Llangefni, in the county of Anglesey; at Saundersfoot, in the county of Pembroke; and at Creetown, in the county of Kirkcudbright.

Births, Marriages, and Deaths.

BIRTHS.

WACHER.—On August 7th, at Chalkwell-gardens, Leigh-on Sea, the wife of Geoffrey Wacher, L.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

SILAS—STANNARD.—On July 31st, at Christ Church, Mayfair, Walter B. Silas, M.R.C.S., L.R.C.P., of Southgate-road, N., to Lilian, daughter of Henry Stannard, R.B.A., of Bedford.

GOLDEN WEDDING.

JONES—MORRIS.—On August 11 [illegible] 's Church Sydenham, by the Rev. C [illegible] Jones, M.D. Lond., F.R.C.S., of St. [illegible] rator of the Pathological Museum, St. Thomas's Hospital, London, eighth son of the late Thomas Jones, Walworth, Surrey, to Mary Myrie, elder daughter of Samuel Morris, Sherwood Lodge, Sydenham, of the firm of Messrs. Bevington and Morris, 28, Cannon-street, London, E.C.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HARMFUL EFFECTS OF ACETANILIDE, ANTIPYRIN, AND PHENACETIN.

A VALUABLE report (Bulletin No 126, Bureau of Chemistry, United States Department of Agriculture, 85 pp , Washington, July, 1909), has just been prepared by Dr. L F Kebler, Dr F. P. Morgan, and Dr. Philip Ruff on the reports of physicians with regard to their personal experience in the use of acetanilide, antipyrin, and phenacetin The objects of the inquiry were similar to those of the Therapeutic Committee of the British Medical Association, which in 1894, *under the chairmanship of Dr. D J. Leech,* concluded that the ill effects of these remedies were very largely the direct result of injudicious and excessive dosage This report made a deep impression upon the medical mind, with the result that smaller doses have been given and the number of accidents reported has fallen off to a remarkable extent. Dr. Kebler and his collaborators addressed a series of questions to 925 physicians and received 400 replies which are summarised in Table I. ;—

TABLE I

	Poisoning.	Deaths.	Habitual use.
Acetanilide	614	16	112
Antipyrin	105	5	7
Phenacetin	95	7	17
	814	28	136

A careful search was also made in the medical literature during the period 1884–1907, and the results of this search are given in Table II. .—

TABLE II

	Poisoning	Deaths.	Habitual use.
Acetanilide	297	13	32
Antipyrin	488	10	—
Phenacetin	70	3	1
	855	26	33

The section on the literature of the subject occupies 60 pages and contains abstracts of the cases referred to It forms a valuable bibliography of the subject. Turning to the details of Dr Kebler's correspondence with physicians, phenacetin was used frequently or moderately by 36 7 per cent of the physicians, acetanilide by 30 per cent , and antipyrin by only 5 per cent Phenacetin is most extensively used because it is generally regarded as being the least harmful *of these substances.* It was *found that the doses of these remedies* employed to day are much smaller than those formerly prescribed. In the case of acetanilide, the replies of 274 physicians indicate that 87 5 per cent of them never prescribe higher doses than five grains, while about *70 per cent. prescribe* antipyrin and phenacetin in doses not exceeding five grains It was also found that from 51 to 66 per cent. of the observers now prescribe these remedies less frequently than formerly Of the 814 cases of poisoning reported, 94 were children, while the drugs were administered without a physician's prescription in 377, or about 46 per cent , of the cases This fact is specially significant in connexion with the ever-increasing sale of hese drugs, and of preparations containing them, to the public In such cases the remedy is taken without the safeguards that *ordinarily* attend the ingestion of medicines when ordered by a physician It is of interest to note that in the case of acetanilide poisoning resulted from its external application in 2 3 per cent. of the cases As regards the quantity taken in cases of *poisoning,* of the *368 cases* in which acetanilide was given to adults a dose of five grains or more was given in 89·9 per cent., with antipyrin a dose of ten or more grains was given in 89 7 per cent. of the cases, while with phenacetin the toxic effects were caused by doses of ten grains or more in 67·8 per cent of the cases In children, in over 85 per cent of the cases the poisonous effects were caused by doses of two grains or more of acetanilide or of three grains or more of antipyrin The report serves to warn physicians that care should be taken in prescribing these substances, even *in relatively small doses.*

THE ALPINE MINOTAUR.

NOT more inexorably did the Cretan monster exact his yearly tribute of the Athenian youth, male and *female* than does his Alpine counterpart—the evil genius of foolhardy adventure—claim his annual toll of victims The summer now passing—nay, the winter and spring already past, have numbered quite as many sacrifices as their predecessors to that ruthless Cacodaemon, who may confidently anticipate—so vainly has experience held out its warning—an equal contingent of such in the years yet to come. The old, old story will keep repeating itself, the amateur "peak-stormer," heedless of the fact that his enterprise demands special training, with special *equipment and guidance, under special conditions of physique* and health, before he can essay it with success or safety, will still venture out and up, in regions unfamiliar, with nothing but curiosity and pluck to sustain him, till, after hours of *exertion,* he *loses his* way, his head, and ultimately his life, overtaken by a mist or overwhelmed by an avalanche, or overbalanced on the brink of a crevasse And this tale, told for the thousandth time, will yet be told for the *thousand and first unless some "deus" or demigod "ex machina,"* in the form of a Theseus in science, aided by the guiding thread of an Ariadne in resource, makes Alpine misadventure and the "Minotaur's" maintenance alike impossible by deterring from pass and peak all but the adequately trained and the physically and mentally "assured" First attempted by the Teutonic races, the exploration of the Alps, unessayed by the Romans on whom the glories of landscape were thrown away, begins with sixteenth century humanism embodied in Conrad Gesner, the Swiss scholar, whose treatise "De Admiratione Montium" may be taken as the "evangel" of mountaineering, scientific and artistic Of late years, however, the French, and particularly the Italian, nature student and athlete has in ever-increasing numbers enrolled himself in the army of Alpine adventurers, attended, however, by such a host of camp followers in the shape of amateurs as to double, nay treble, the casualties that have hitherto overtaken even the regular recruit. "Impressionanti Disgrazie sulle Alpi" (sensational accidents on the Alps) is the heading in a leading Roman journal of a series of fatalities occurring within the last week of July, mainly to Italian [illegible] xperience the well nigh inevitable [illegible] ardous of all enterprises with less [illegible] recklessness than either. Signor [illegible] e, having gained a "coign of vantage" on the Diveria at the Bridge of Crevalodossola fell headlong to the bottom, where he was found a corpse Signor Andrea Consoli, another youth of 21 years, *overtaken* on the Majenfeldfurku by a furious snowstorm, was frozen to death; and so on in many cases, the rash attempt to pluck a flower on the margin of a precipice, or to root out a mineralogical specimen from a rocky façade, having carried the Alpinista over the edge or crushed him under a "Steinschuss" Such casualties, it may be said, will be minimised by the "vicarious progression" afforded on funicular or cog wheel railway Possibly, but that means of gaining altitudes above the snow line has dangers of its own, recorded and illustrated *at many a Swiss medical congress, memorably in that at Arosa some* 10 or 12 years ago Middle aged tourists, with cardiac lesion incipient or developed, could run few greater risks than that of being "ballooned" up a mountain side like that *of the Jungfrau* or (*now it seems likely*) *Mont Blanc*—some of them realising for the first time, in distress and panic, that they had such a thing as a heart at all! "Knowledge comes, but wisdom lingers", and even with the admonitions of medical science we are quite prepared to hear of the holiday-seeker, tempted by the "ampler ether,' the "diviner air," of a resort above the snow-line, throwing prudence to the winds, and essaying a "vicarious ascent" safe only for the young and the heart whole!

> "Audax omnia perpeti
> Gens humana ruit per vetitum nefas ;"

and before the century is much older we may have aerial navigation seducing many a holiday or health-seeker on a voyage confronted by unforeseen dangers, the multiplication of which may inspire medical congresses to discussions and admonitions even graver, if not less idle, than those convened to convince of his folly the middle-aged "altitudinarian"

BAGS AND BOTTLES

WITH the arrival of the holiday season we are tempted to ask a question which has probably occurred to many *of* our readers when looking out their baggage in preparation for leaving home, or perhaps when passing a trunk maker's shop window with its well ordered display of leather goods Whilst the first glance at an open trunk or portmanteau can leave no doubt of the function of its every part, the dressing bag, and in some cases the suit case—most convenient of impedimenta—*if they belong to the more expensive class, present* as soon as they are opened a problem on which we seek enlightenment, What did their maker intend their user to put in the array of bottles which they contain? We do not exaggerate in computing that a completely fitted dressing-case carries in addition to its complement of brushes, razors, and mirror, from eight to a dozen glass bottles, and boxes often with decorative lids or tops We will acknowledge that they look very pretty and that a bag thus equipped forms what is known as an "attractive and handsome present," but *the only person to whom we can conceive it as being of the fullest* use is the fashionable obstetrician Such a receptacle would be both [illegible] the polite *chambre d'accouchement* for it [illegible] nt [illegible] ck [illegible] — [illegible] ne thing does not apply to the surgeon, whose preparations are made out of his patient's sight, and the modern physician, if he carry drugs at all, does so in the compressed form convenient for their hypodermic employment But the great majority of people who own fitted dressing cases are not members of the medical profession, and it is an interesting speculation as to why the upper travelling classes came *in the first instance to be supplied* with so many bottles We suspect that these fitted bags had their origin in days when travel was a more adventurous affair than it is at present and that a certain number of the bottles were intended to hold simple drugs for emergency use—"the spirit of hartshorn" for example, or an aperient draught. Perhaps some people still fill them with such preparations, though probably the tablet drug in the pocket has taken the place of the case of liquid medicines. If our surmise is correct the bag-maker has not advanced his ideas with those of the drug purveyor, but with the conservatism notable in so many trades he continues to supply an article on the model which his grandfather made to a generation that has forgotten its use. Perhaps we are wrong, and people really exist who require a dozen bottles to hold the *arcana* of their daily toilet. But when soap, shaving-soap, tooth-powder, and possibly a preparation for the hair have been provided for, we are at a loss to know how the average man is to fill the rest of the bottles and boxes. We might allow a couple for scent to a lady who affects it, but cannot suppose its most extravagant user to carry a different perfume for every day of the week. Of cosmetics we speak with little knowledge; perhaps they to some extent solve the mystery, but they can hardly find a place in the masculine dressing-case; and we are convinced that whatever be the origin or supposed function of the receptacles in question the average man whose bag contains them would prefer their room to their company.

THE HISTORY OF COLCHICUM.

THE history of colchicum is the subject of a readable article by Dr. J. Gordon Sharp in the *Pharmaceutical Journal* of July 3rd. The name colchicum is derived from Colchis, a district of Asia Minor, now known as Mingrelia and Abasia. The ancient Colchis conveyed to the Greek mind a region associated with all kinds of sorcery, and so any drug coming from it was likely to be held in awe by the ignorant and in discredit by the learned. It is doubtful whether the species Colchicum autumnale grew in Colchis, but it is evident that whatever the species that were employed they were rich in colchicine, judging from the accounts of the value of the drug in articular affections of gouty origin. There is evidence that the "hermodactyl" of the Arabs and the "surinjan" of the Indian bazaars were species of colchicum. It is probable that the drug first became known in Europe shortly before it was described by Dioscorides, or about 78 A.D. The earliest mention of the drug is in the "Ebers Papyrus" (1550 B.C.). Under the name "hermodactyl" the drug was mentioned by Alexander of Tralles in "The Twelve Books of Medicine" (560 A.D.), and Paul of Ægina, in the seventh century, fully described hermodactyl and spoke of its efficacy in gout. Avicenna, the greatest of all Persian physicians (980–1037 A.D.), gave his personal testimony to the value of the drug, and in the thirteenth century Demetrius Pepagomenus, a Greek physician, wrote a treatise on gout and gave the formula of a pill composed of hermodactyl, aloes, and cinnamon. With the distrust of Arab medicine that followed from the thirteenth to the sixteenth century but little was heard of hermodactyl, and under the name colchicum the drug was condemned as dangerous by several writers, and it was ignored altogether by many others, including Culpepper (1616–1652) and the great Sydenham. As so frequently happens, however, a reaction then set in, and during the eighteenth century writers began to suggest that after all there might be some value in the drug. It was official under both names in the London Pharmacopœia of 1618, and one or both names were recognised in succeeding editions up to 1639. An interval of 149 years then elapsed until 1788, when colchicum was made official and the name hermodactyl disappeared. It is interesting to note that colchicum wine was first introduced in 1780 as a secret preparation by Husson, an officer in the French army, and was sold under the name "Eau Médicinale." It attained a great popularity and was largely imitated. Scudamore (1779–1849) wrote largely on gout and its treatment by colchicum, and ever since the drug has occupied an important position in the materia medica. Referring to the modern use of colchicum, Dr. Sharp remarks that the official doses are often exceeded owing to the belief that the drug acts best in doses bordering on the toxic side. The alkaloid is not largely employed, although the salicylate is occasionally prescribed in the form of pills or in solution in methyl salicylate. He suggests that colchicine salicylate will probably be more largely prescribed in future in the form of an ointment to be applied to affected joints.

HISTORICAL RESEARCHES ON SYPHILIS.

To the Editor of THE LANCET.

SIR,—I do not think the attempt of Dr. Kronfeld of Vienna to prove the antiquity of syphilis from the examination of an ancient Greek vase can be considered convincing. In a paper that he read before the Gesellschaft der Aerzte (reported in THE LANCET of July 31st, p. 333) he describes a Greek vase of the seventh or eighth century B.C. which showed very clearly a dark-coloured woman of negroid type presenting "chronic serpiginous ulcerations on her arms and legs," and concluded somewhat hastily that syphilitic lesions were depicted. Sufficient consideration, perhaps, was not given to the fact that there are several examples among Greek and Roman fictile vases in which the dark colouring matter employed by the potter had "run" and in process of time became distorted or obliterated. It may be suggested that in this manner the appearance of the figure examined by Dr. Kronfeld can be explained. Authentic material for elucidating in some measure the lineage of the disease, which so curiously obtained its name from a poem published at Verona in the fifteenth century (*Syphilis sive Morbus Gallicus*, by Jerone Fracastoro), may be found in historical records. In no account of the disease that I have read is there any reference to Herodotus. That historian says that the Scythians of his day suffered from "a severe female distemper," and that it was regarded by the nation as a divine punishment inflicted on their ancestors for having in the course of a predatory raid plundered the famous temple of the Syrian Venus (Derceto) at Ascalon. There are fragmentary passages in other ancient writers from which it would appear that at the dawn of history the people of Athens were afflicted with a virulent disease of the genital organs which they ascribed to the vengeance of Bacchus for the negligent or insufficient observance of the festivals in his honour, the Dionysia and Phallica. With the view of appeasing the offended deity these orgiastic ceremonies, which were probably borrowed from the Egyptian worship of Osiris, were re-instituted with great solemnity in Athens, a wooden representation of the phallus being carried in procession by men specially dedicated to the service. On reading the epigrams of Martial, and bearing in mind what is known from other sources of the social conditions then prevailing in the Suburra district of Rome, it is easy to imagine that ravages caused by the spirochæta pallida were described by that very acute observer.

I am, Sir, yours faithfully,

Worthing, August 7th, 1909. W. W. J.

AMATEUR PRINTING AS A HOBBY FOR MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—May I, through the medium of your columns, suggest that if any of your readers happen to be amateur printers they should put themselves in communication with me? I would gladly supply information. Medical men find this hobby useful in a variety of ways (e.g., memoranda, lecture syllabuses, labels, bills), in addition to the artistic taste to which it ministers.

I am, Sir, yours faithfully,
E. H. BLAKENEY,
Hon. Secretary, Amateur Printers' Association.

Ely, August 9th, 1909.

◆

Corrigendum.—In a report of the proceedings of the Central Midwives Board on p. 409 of THE LANCET of August 7th, the third sentence of the "Leaflet" on ophthalmia neonatorum begins "It generally arises." We are asked to say that this should read "The disease generally arises."

L.R.C.S. is advised not to enter into any such negotiation. His position as a medical man might, under the proposed agreement, be used to give a professional colouring to some very dubious proceedings.

Enamel.—We have no knowledge of the preparation in question, but if our correspondent will forward us a sample we shall be pleased to analyse it.

A Widow has neglected to supply us with her name and address. If these are sent we may be able to forward her wishes.

Perplexed has failed to entrust us with his name. The communication is of considerable interest.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

[illegible] *private information* [illegible] *d addresses of* [illegible]

[illegible] *phs should be marked and addressed "To the Sub-Editor."*

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol I of 1909, which was completed with the issue of June 26th, and the Title-page to the volume, were given in THE LANCET of July 3rd

VOLUMES AND CASES

VOLUMES for the first half of the year 1909 are n ready. Bound in cloth, gilt lettered, price 18*s*, carria extra

Cases for binding the half-year's numbers are also read Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompani by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptio which are sent direct to the Proprietors of THE LANCET their Offices, 423, Strand, London, W.C, are dealt with them? Subscriptions paid to London or to local newsagen (with none of whom have the Proprietors any connexion wha ever) do not reach THE LANCET Offices, and consequent inquiries concerning missing copies, &c, should be sent the Agent to whom the subscription is paid, and *not* THE LANCET Offices

Subscribers, by sending their subscriptions direct THE LANCET Offices, will insure regularity in the despat of their Journals and an earlier delivery than the majori of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on th paper) is published in time to catch the weekly Friday mail to all parts of the world

The rates of subscriptions, post free, either fro THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM				TO THE COLONIES AND ABROAD			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months .	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) a payable in advance Cheques and Post Office Orders (crosse "London and Westminster Bank, Westminster Branch" should be made payable to the Manager, Mr. CHARLES GOO THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS *ABROAD ARE PARTICULARLY REQUESTE* TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. I has come to the knowledge of the Manager that in som cases higher rates are being charged, on the plea that th heavy weight of THE LANCET necessitates additiona postage above the ordinary rate allowed for in the terms o subscriptions. Any demand for increased rates, on this or o any other ground, should be resisted The Proprietors o THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of [illegible] issues; and Agents are author [illegible] do so collect, from the Propr [illegible] postage

The Manager will be pleased to forward copies direct fron the Offices to places abroad at the above rates, whatever b the weight of any of the copies so supplied Address— THE MANAGER, THE LANCET OFFICES, 423, STRAND LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs WILLIAM WOO AND CO, 51, Fifth Avenue, New York, U S A.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

An Address

ON

THE PRESENT STATE OF OUR KNOWLEDGE OF THE BACTERIOLOGY AND PATHOLOGICAL ANATOMY OF LEPROSY.

Delivered at the Second International Scientific Congress on Leprosy (to open the Discussion on the Pathological Anatomy of Leprosy) held at Bergen, August 16th to 19th, 1909,

BY J. M. H. MACLEOD, M.A. ST. AND., M.D. ABERD., M.R.C.P. LOND.,

LECTURER ON SKIN DISEASES, LONDON SCHOOL OF TROPICAL MEDICINE, PHYSICIAN FOR DISEASES OF THE SKIN (OUT-PATIENTS), CHARING CROSS HOSPITAL AND VICTORIA HOSPITAL FOR CHILDREN, LONDON.

MR. PRESIDENT AND GENTLEMEN,—When the Committee of Organisation of the Second International Scientific Congress on Leprosy invited me to open the discussion on the Pathological Anatomy of Leprosy I felt that a great honour had been conferred not only on myself but also on the London School of Tropical Medicine, whose delegate I am. At the same time I could not but feel the responsibility of the position, and would greatly have preferred that the task had fallen to someone of wider experience. At the first International Scientific Congress on Leprosy, held in Berlin in 1897, this duty was performed by the late Rudolf Virchow. The loss the world has sustained by his death cannot be over-estimated; but his influence and his teaching are a permanent heritage. Only to the few has it been given to leave their indelible imprint on the science of medicine for all time; to none more than to him. Since the first Congress in 1897 almost all the advances which have been made with regard to leprosy have been the result of a [illegible] thology and bacteriology of the di[illegible] nce has not been rapid, nor assc[illegible] or epoch-marking discovery, it has been none the less sure. In the short time at my disposal it will be my endeavour to point out wherein this advance has taken place, to state briefly the present position of our knowledge of the bacteriology and pathology of the disease, to show wherein that knowledge is defective, and to suggest certain questions for discussion.

THE CAUSE OF THE DISEASE: THE LEPRA BACILLUS.

The researches of the last 12 years, since the first Lepra Congress, have only more firmly established the lepra bacillus of Hansen as the specific cause of leprosy; although up to the present time all the postulates of Koch have not been fulfilled by it, yet the fact that it occurs universally in leprosy in all its forms, that all the symptoms of leprosy can be explained as the direct or indirect result of a pathological process produced by it, that it is absent in all other morbid entities, and that it possesses characteristics which differentiat[illegible] render its position as [illegible] that of the plasmodium [illegible] ng fever.

Morphology.—The knowledge of the morphology of the bacillus has been advanced of late by the introduction of special staining methods to demonstrate the young homogeneous bacilli, the old, granular and dead bacilli, the resistant fat in the bacilli, and the fat in the glœa which holds them together. By these methods it has been shown that a large proportion of the bacilli in the tissue are dead, that even in young newly-formed lepromata dead bacilli occur, while in older lesions the majority of the bacilli are dead. By Ziehl's method, using 20 per cent. nitric acid and counter-staining with polychrome blue, young bacilli are stained red, older bacilli violet, and granular bacilli blue. Emile-Weil[1] suggested the employment of the Baumgarten method, namely, staining with aniline violet in the cold, and using nitric alcohol (1 in 10) to differentiate. By this means the bacillus does not lose its stain. Unna,[2] for the double staining of normal and dead bacilli in the tissues, suggested the employment of Victoria blue, 1 per cent. nitric acid, and saffranin; this stains the normal bacilli blue and the dead bacilli yellow. The differentiation by means of staining methods of the lepra bacillus from the tubercle bacillus is uncertain, though various methods have been suggested, based on the fact that the lepra bacilli, when stained by Ziehl's method, more readily lose their stain when treated with nitric acid than the tubercle bacilli, and we are compelled to fall back on other characteristics to distinguish them.

Classification.—The classification of the lepra bacillus is a matter for discussion at the present time. Until recently the bacillus was believed to belong to the class of schizomycetes, but the finding of a cladothrix arrangement by Barranikow and others,[3] and of branching forms like actinomyces, have rendered it probable that it belongs to the class of the streptotricheæ. In the bacilli small spheres have been noticed, and have been described as "spores," but the evidence that they are true spores is not conclusive.

Cultivation.—In spite of the numerous attempts which have been made during the last decade to cultivate the bacillus, no medium has been discovered on which it will invariably grow. From time to time observers have announced that they have succeeded in cultivating it, but further experiments by themselves or others have usually failed to establish their claim, and showed that either the technique was defective, that the cultivations had become contaminated, or that some other acid-fast micro-organism, like the tubercle bacillus, had been grown. Of the many attempts to cultivate the lepra bacillus claimed to have been successful, but which have not been definitely established, three may be mentioned. 1. Carrasquilla[4] reported that he had cultivated the lepra bacillus on human blood serum and on beef bouillon. 2. Van Houtum[5] recorded positive results on broth prepared with fish and beef, and rendered alkaline with leprous material. He also claimed that the bacilli, when mixed with diluted human serum, showed the Pfeiffer-Bordet reaction with destruction of bacilli, which was more marked with leprous serum than with ordinary serum. 3. Emile-Weil,[6] working in the laboratory of the St. Louis Hospital, Paris, under M. Sabouraud, claimed to have cultivated lepra bacilli from recent leprous nodules on several peptone-glucose and peptone-agar media containing pleuritic serum. His apparently most successful experiment was by inoculating leprous material in a hen's egg as follows. The juice from a recent nodule was taken up by a pipette. This was introduced into the yolk after piercing the broad end of the egg. The small hole was afterwards closed up by a collodion scab and the egg incubated at 37°. The yolk was then turned out on a Petri dish, and in it a small yellowish nodule about the size of a hemp seed was observed, which proved to be a colony of lepra bacilli. This result was obtained twice out of 26 eggs inoculated.

Up to the present not only has no satisfactory medium been found on which the lepra bacillus will grow, but it has not been proved that the bacillus is present and can lead a saprophytic existence on decayed organic matter, such as decayed fish, meat, rice, or in the soil. If the bacillus could lead such a saprophytic existence there should be no great [illegible] found to exist in decayed fish and to be capable of being recognised there, the fish theory of the etiology of leprosy cannot be regarded as other than a hypothesis which is unsupported by scientific fact.

Inoculation.—Up to the present time no lower animal has been found which is susceptible to leprosy. Numerous inoculation experiments have been made on different animals, chiefly monkeys, rabbits, and guinea-pigs, the leprous material being inoculated under the skin, in the peritoneal cavity, in the anterior chamber of the eye, &c., but invariably with negative results. Nicolle of Tunis[7] excised a nodule from a leper. This was broken down, diluted with sterile water, and inoculated on the temples of a monkey after scarification, also on the conjunctiva, nasal mucosa, and on the left ear under the skin. A Macacus ape was similarly inoculated. Four days afterwards all traces of the inoculations had gone and an examination of the nasal mucus showed no bacilli. A month later a small subcutaneous nodule appeared in front of the ear and a few days afterwards one or two small, indurated, red nodules in the auricle. These remained unaltered for some time. A histological examination showed an accumulation of lymphocytes but no giant cells or caseation. The bacilli in the tissue were few and were almost all in the cells. There was no definite "lepra cells."

Presence of lepra bacillus in insects.—So far the microbe has not been found in mosquitoes, nor in other insects suspected of disseminating the disease, though in this connexion Goodhue[8] claims to have found the bacillus in the gnat and the bed-bug (*Cimex lectularis*). This observation, so far as I am aware, has not been corroborated by others.

Serology.—An immunising serum has not yet been obtained for leprosy, and all attempts to extract from lepromata a substance which would produce in leprous patients a reaction analogous to that produced by tuberculin in tuberculous patients have been unsuccessful. It is a well-known fact that leprous patients may react to the old tuberculin, but this reaction is of comparatively little significance, as individuals may react to the old tuberculin without being tuberculous. Leprous patients also react to the products of other micro-organisms. The Carrasquilla serum method has not fulfilled its promise, and the results from it have been so disappointing that it has been practically abandoned. The method was as follows. Blood was obtained from leper cases by venesection performed on the patients at the febrile period when the blood was at its maximum toxicity. From this a leprous serum was separated and injected a few hours after collection into a horse, three injections being given at intervals of ten days. From this horse after ten days a serum was obtained, which was injected into the patient. Tidswell[9] gave a careful account of his experience with the serum, and reported unfavourably regarding it. He found that with injections of 5 cubic centimetres in the human subject, injected every three to five days for a period of nine months, no marked reaction was produced, and no rigor, fever, joint pains, or erythema occurred. At first the patients said they felt better, but, as is usually the case with a new remedy, when they got accustomed to it, they became as listless as before. No change in the nodules and macules were detected; anæsthesia persisted, alopecia and defects of sight were not improved, and the disease did not seem to be ameliorated or arrested. After nine months' trial the patients declined to submit to further treatment with the serum. Rost, in 1904,[10] claimed to have succeeded in cultivating the lepra bacillus in an achloretic medium, and to have produced from it a "leprolin," made on the same principles as Koch's tuberculin. The bacillus which was cultivated, however, did not prove to be the lepra bacillus, and the reaction produced by the so-called "leprolin" when injected was possibly due to "filtered toxins from the contaminated media" (Semple). In the same year Deycke[11] succeeded in cultivating a streptothrix from cases of nodular leprosy. This streptothrix he did not consider to be the lepra bacillus, but from it a well-defined neutral fat was extracted by ether, to which the name "nastin" was given. This, when combined with benzoyl chloride and injected, produced a bacteriolysis, and was said to cause an arrest of the leprous process.

MODE OF INVASION.

The path of entrance of the lepra bacillus is a point of importance with regard to the prophylaxis of the disease, but it is still *sub judice*. It would seem most probable that the bacillus may gain entrance in various ways. Probably the most common mode of invasion is *viâ* the *nasal mucosa and upper respiratory tract*. This view is corroborated by the frequency with which nasal symptoms form one of the earliest manifestations of the disease, such as rhinitis, chronic coryza, ozæna, epistaxis, lepromata in the nasal mucosa, and the presence of lepra bacilli in the nasal discharge. Kolle[12] examined the nasal mucosa of 137 lepers for bacilli at Robben Island. He found bacilli in the mucus in all the 45 nodular cases. In 30 cases of mixed leprosy bacilli were found in the nasal mucus in 22. In 60 anæsthetic cases he only found the bacillus in the nose in 21. In 30 cases no bacilli were found in the nasal mucosa, but in two of these they were found in the sputum. The lepra bacilli may also gain entrance *viâ the mouth* and infect the tonsils, and they have been found in the sputum. With regard to the *alimentary tract* being a path of infection, the evidence at the present time is less conclusive. Nothing suggestive of an initial lesion producing definite symptoms has been located there, nor has the bacillus been found in food-stuffs, except in the human milk. The invasion of the bacilli may take place through the *skin*, especially when the stratum corneum has been abraded by traumatism, or its resistance lowered by some form of dermatitis. The *genital organs* may also be the means by which the bacillus gains entrance, and in this case the infection probably takes place from lepromata situated on the penis or in the vagina. Although the testicles are frequently involved there is no distinct evidence of infection from the semen. Congenital leprosy has not been proved to occur, and in this the disease shows a strict parallelism with tuberculosis, for infants of leprous parents are not born with leprosy, but may become infected subsequently as a result of a hereditary weakness or predisposition and an existence in an environment in which contagion is liable to occur.

MODE OF DISSEMINATION OF THE LEPRA BACILLI AFTER INVASION.

After gaining entrance the lepra bacilli may be found widely distributed throughout certain of the tissues of the body. They may occur in the skin, eyes, mucous membranes, lymphatic glands, viscera, and peripheral nerves. They are absent from the muscles, bones, and joints. They do not occur in physiological secretions unless pathologically contaminated. According as the bacilli show a special predilection for the peripheral nerves in contra-distinction to a more general invasion of the tissues, with the formation of nodules or lepromata in the skin and viscera, so the two great types of the disease are produced—namely, the maculo-anæsthetic and the nodular type.

Relation of maculo-anæsthetic and nodular leprosy.—The question of the relation of maculo-anæsthetic leprosy to nodular leprosy raises certain important problems with regard to the pathology of the disease. At the present time the precise conditions which determine that a case should pertain to the one type or the other are imperfectly understood. Various hypotheses have been advanced to explain it. It has been asserted, for example, that the variation in type is simply the result of a *quantitative* [illegible] bacilli, and that where the bacilli occur in large numbers nodular leprosy results, while if the bacilli are few the manifestations are those of the maculo-anæsthetic type. This explanation is not convincing, because in the mildest cases of nodular leprosy large numbers of bacilli occur, while in the most severe cases of maculo-anæsthetic leprosy fewer bacilli may be found in the nerves, and the most careful search for them in the viscera and in the maculo-anæsthetic patches may give negative results. The cause of the vast proliferation of bacilli in the nodular cases is uncertain. Is it a racial peculiarity? Is it the result of climatic conditions? Is there a hereditary or acquired immunity by which an individual is rendered an unsuitable soil for the propagation of the bacilli, so that only the peripheral nervous system remains markedly susceptible? It has been suggested, on the other hand, that the difference in type of case is the result of a *qualitative difference in virulence of the bacilli*, and that when virulent bacilli are present nodular leprosy is produced, but where the bacilli are of low virulence maculo-anæsthetic leprosy results.

SOME CONSIDERATIONS ON THE HISTO-PATHOLOGY OF THE LESIONS PRODUCED IN THE TISSUES BY THE DIRECT OR INDIRECT ACTION OF THE LEPRA BACILLI.

After gaining entrance into a tissue the bacilli appear to lie at first in the lymph spaces, and owing to their presence produce a mild inflammatory reaction. In comparison with that caused by the tubercle bacillus this reaction is slight,

[illegible] existence a peculiar type of [illegible] peculiarities wh[illegible] infiltration is [illegible] spindle-shaped [illegible] fixed tissue and the adventitia and endothelium of the bloo[illegible] cells, and occasional polynucl[illegible]nic micro-organisms be pre[illegible] of the bacilli is mainly [illegible] multiply they form colonies or globi united by homogeneous zoogloea, and the infiltration begins to show the presence of plasma cells around the blood capillaries. A certain number of bacilli become intracellular, and large characteristic cells containing vacuoles, one or more badly stained nuclei, and bacilli singly or in clumps may be noted. These are the so-called "lepra cells," on the origin of which there has been much diversity of opinion as to (1) whether they are really cells derived from connective-tissue cells or plasma cells through the presence and action of the bacillus and its toxin within them; (2) whether they are sections of lines of bacilli lying in the lymphatic spaces; or (3) are simply clusters of bacilli round a lymphocyte or other cell. Certain of the "lepra cells" are enlarged and contain several nuclei, forming a type of giant cell which is different from the Langhans's giant cell of tuberculosis, in that it has neither the [illegible] observations it is necessary to be certain that a mixed infection with tuberculosis did not exist. The bacilli enter and spread slowly through the lymphatics, forming new leprous deposits wherever they go, or they are more quickly distributed to neighbouring and distant parts by the blood-stream. The above, in brief, is the type of cellular infiltration of the "leproma," wherever it may be situated in the body.

In [illegible]en confined, as a rule, to th[illegible] a thin layer which is free [illegible] the epidermis. One or two observers have detected bacilli in the deeper layer of the epidermis in and between the prickle-cells, and also in the *corresponding layer of the hair-follicles*, but it is doubtful if they exist in the sebaceous glands, as they have an aversion to fat. More important as regards the spread of the disease is the fact that bacilli have been found on the surface of the epidermis and in the scales. It is doubtful, however, if [illegible] surface from within, and it is [illegible]ey have been deposited there [illegible] from the upper respiratory [illegible]hing. It is possible also that they may have been eliminated by the sweat, as they have been found both in the sweat and the sweat glands. The presence of bacilli in the small cutaneous nerves, and the changes produced by them, are responsible for the alteration [illegible] nodule. The pathological [illegible] leprosy is of the same type [illegible]es, but it appears later and [illegible]

[illegible]*cera.*—With regard to the leprous changes in the viscera little has been added to our knowledge since the last congress. *In the spleen, in addition* to the leprous infiltrations in the trabeculæ, pulp, and [illegible]necrotic masses have been [illegible] tuberculosis with typical [illegible]ses have to be further verified from the point of view of tuberculosis before they can be finally accepted. The involvement of the *genitalia* is a matter of great importance with regard to the spreading of the disease, but there still remain certain gaps in our knowledge on this subject. On the penis nodules and flat infiltrations or ulcers with pus and bacilli have been observed from time to t[illegible] of 40 cases.[14] [illegible] between the [illegible] tubules thems[illegible] evidence that the semen contains bacilli. The atrophy which succeeds the sclerosis results in sterility. It is much the same with the ovaries. The presence of the bacilli [illegible] urine. In the *lungs* a pure leprous infiltration may exist, with sma[illegible] vascular [illegible] cells of [illegible] indicatin[illegible] *lymphatic glands*, like the lungs, may be the seat of a mixed infection with tuberculosis, and show caseation and other signs of it; on the other hand, a pure leprous infiltration may occur.

Although the changes in t[illegible] well known, and bacilli hav[illegible] cells, the *blood* changes ha[illegible] out. Bacilli have been de[illegible] during the active stages o[illegible] observers (Köbner, Wolters, [illegible] They were either lying free o[illegible] The blood changes are not [illegible] those of chlorosis, and are [illegible] ciated with the disease. Eo[illegible] Gaucher, Bensaude, and others. *Note.*—In making blood-[illegible]osy it is important to avoid [illegible]

[illegible] advance has been made [illegible]rosy of the eyes. It is one [illegible]nodular leprosy, and occurs usually after the face, eyebrows, and eyelids have been affected, and it is rarely a primary manifestation. Apart from the involvement of the eye due to pyogenic micro-organisms or injury where the cornea is anæsthetic, or the [illegible] spreads from within outwards or passes in from the outside. Until lately the generally accepted view has been that the [illegible] deeper parts.

In a recent paper on the subject Calderaro[16] advocates the [illegible]without. According [illegible] spreads on to the globe from the margins of the eyelids, where he found numerous bacilli, even when the [illegible] The first signs of this infection [illegible] infiltration of the conjunctiva, a [illegible] gradually became converted into leprous tissue. The sclero-corneal limbus was next attacked, and a diffuse opacity of the cornea occurred, sometimes associated with the presence of small bullæ containing a dirty yellow fluid. The sclerotic [illegible]many years, [illegible] it bacilli [illegible]veal tract. [illegible]and the iris [illegible]read far in the choroid and the retina and optic nerve were seldom [illegible]blindness occurred.

[illegible]servers are at one with regard to the essential features of the histological architecture of the lesions in nodular leprosy, there is still a diversity of opinion with regard to the histo-pathology of the patches in maculo-anæsthetic leprosy. It has been suggested on the one hand that these patches have the same [illegible]only less pronounced, [illegible] in the evolution of [illegible]wever, is not borne [illegible] do not begin with [illegible]ulo-anæsthetic lesions. On the other hand, it has been [illegible]rted that they are totally different from the lepromatous nodules, the one being an infective granuloma, while the

[16] La Clin. Oculist, 1909.

other is in the nature of a persistent inflammatory process of the type of erythema perstans. The second suggestion appears to me to be the more probable. At first an erythema occurs which is followed by a slight infiltration of round and spindle-cells about the capillaries, sweat-glands, and hair-follicles, and a deposit of pigment in the perivascular cells. In association with this infiltration no true "lepra cells" can be detected. This process is centrifugal in its evolution, tending to disappear in the centre, so that ringed lesions may result.

The chief point at issue is the manner in which these changes are brought about. Certain observers believe them to be "neuro-leprides," and to be indirectly produced by the action of the bacilli on the nerves supplying the area affected, in the same way as the bullæ of nerve leprosy. Others regard them as the result of toxins eliminated by bacilli situated at a distance from the skin and circulating in the cutaneous capillaries, and as corresponding to the "tuberculides" of Darier. Others, again, consider them to be due to the action of the toxins of the bacillus *in situ*, and regard the nerve-change as secondary.

In consequence of these diverse opinions much interest has been centred round the question of the presence or absence of the bacilli in the maculo-anæsthetic patches. Some observers, such as Looft, Hansen, Pollitzer, and Klingmüller, have succeeded in finding bacilli in these patches situated in the endothelium and about the capillaries of the skin. There are others, however, who after the most patient search have failed to find them in true maculo-anæsthetic patches, while they have found them in slightly infiltrated lesions. A single definite instance, however, of bacilli being found in a true maculo-anæsthetic patch is of more value than all the negative evidence. After all, it may be extremely difficult to find bacilli in a patch of lupus vulgaris, and yet no one would deny that they are present and cause the affection. But when it is remembered that the lepra bacillus, unlike the tubercle bacillus, is a comparatively feeble micro-organism, and even in vast numbers may produce extraordinarily little reaction in the tissues, a doubt is raised as to whether a few lepra bacilli occurring in the skin are capable of causing a maculo-anæsthetic patch. It has been asserted that the bacilli are only present in the maculo-anæsthetic lesions at first and disappear from them later into the peripheral nerve-endings, and finally ascend into the peripheral nerves. This assertion has been put forward to explain the failure to find bacilli in the patches.[17] The *peripheral nerves* may be involved in all forms of leprosy, but it is in the maculo-anæsthetic type that the involvement is most marked and rapid. In this type of leprosy it would appear that the site of diminished resistance to the bacillus is *par excellence* the peripheral nervous system.

Much good work has been done recently in connexion with *nerve leprosy*, and considerable advance has been made in our knowledge of the subject. All leprologists are agreed that the lepra bacilli may affect the nerves in their whole course, but there is no unanimity with regard to the mode of invasion, and opinions are divided as to whether the nerve infection occurs first in the finer endings in the skin and ascends, or is a descending process, the result of a general infection.

Lie, in his excellent monograph,[18] supports the view that the nerve-endings in the skin are first attacked and that this is succeeded by an ascending neuritis. It is difficult to establish this hypothesis definitely as the earliest lesions are not observed microscopically, and the first changes to be detected have been in the peripheral nerves in the form of leprous infiltrations about the vessels of the perineurium and the endoneurium. The epineurium is not, as a rule, affected, unless from traumatism in exposed situations such as the elbow. The bacilli may be within the connective-tissue cells or plasma cells, or may lie free in the lymphatic spaces. Between the nerve fibres they tend to occur in rows rather than in clumps or globi. They have been observed in the neurilemma and the sheath of Schwann,[19] but they have not been detected in the axis-cylinder of the nerves. The presence of the bacilli and their toxins lead to neuritis and interstitial proliferative changes, which, by pressure on the vital nerve tissue, cause degeneration and a fragmentation of the axis-cylinder. Although the bacilli are present in large numbers in the nerve tissue they do not occur in such masses as in lepromata.

It has been asserted that the painful neuritis set up by the bacillus leads to its eventual destruction, so that nerve leprosy is, in a fashion, self-curable. This is a hypothesis of considerable interest, as it would mean, if it were true, that many maculo-anæsthetic lepers, in whom the disease is of old standing and appears to be quiescent, are in a sense cured, the actual virus of the disease being no longer present, only the effects in the form of anæsthetic patches or trophic lesions. This is a point well worthy of discussion.

There is a great diversity of opinion with regard to the presence of the lepra bacillus in the *cord and spinal ganglia*. Certain changes occur in association with leprosy in the posterior columns of the cord at a certain stage in the development of the disease. These changes are not due to the bacillus *in situ*, nor are they characteristic of leprosy. They are more in the nature of the changes which follow the ascending degeneration of a peripheral nerve after injury. It has even been suggested that they are not due to either bacilli or ascending neuritis, but simply result from the general cachexia attendant on the final stages of the disease. Babes claims to have found bacilli in the motor cells of the anterior horns and in the cells of the spinal ganglia. The changes, however, in the anterior horns are too slight and inconstant to account for the state of the motor roots and for the degeneration of the motor nerves. The changes in the peripheral nerve system are responsible for the trophic disturbances associated with nerve leprosy; for the atrophic, weakly resistant skin, which is so liable to infection with pyogenic micro-organisms and to the formation of unhealthy ulcers; for the bullous eruptions, suppression of the sweat, vaso-motor disturbances like Raynaud's disease, loss of power and atrophy of the muscles, and necrotic changes in the bones. In addition to these direct effects, the devitalisation which results from the defective circulation renders the consequences of injury much more severe and retards recovery.

In conclusion, I would emphasise the importance of recognising the possibility of the *association of leprosy with other diseases* in the same individual and at the same time. Many mistakes have occurred from failure to recognise this possibility, and from regarding every symptom in a leper as being due to the lepra bacillus. Just as syphilis may occur in association with other affections, so may leprosy. The association of leprosy and tuberculosis has been frequently noted in the case of the lungs, and yet there has been a tendency to overlook this possibility elsewhere, and before regarding the caseation with Langhans's giant cells, which has been described in the spleen, lymphatics, and skin, as manifestations of leprosy, it is essential to eliminate by inoculation experiments the possibility of a mixed infection with tuberculosis. In the case of maculo-anæsthetic leprosy, in which psoriasis-like patches have been described, before regarding these as leprous changes it is well to consider the possibility of psoriasis and leprosy occurring together. It is not unusual to find psoriasis and syphilis together, and there is no reason why a common skin affection like psoriasis should not occur in a leper. The simultaneous occurrence of leprosy and syphilis, *though* unusual, has also been observed.

GUARDIANS AND MEDICAL OFFICERS.—It was recently proposed by the Chorlton-cum-Hardy board of guardians that representations should be made to the Local Government Board in favour of allowing all medical men to act as district medical officers and public vaccinators, payment for their services to be made according to a scale to be fixed by the guardians. This scheme was brought before a meeting of the finance and general purposes committee of the Salford guardians on August 13th. One of the guardians said the system was in operation in Scotland, and suggested that further inquiry should be made. Another gentleman said the resolution of the Chorlton union was brought forward by the Socialist section of the board, and moved that no action be taken. He thought that such a system would open the door to a good deal of corruption. The motion was not adopted.

The Hunterian Lectures
ON
MALFORMATIONS OF THE HEART.

Delivered before the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1909,

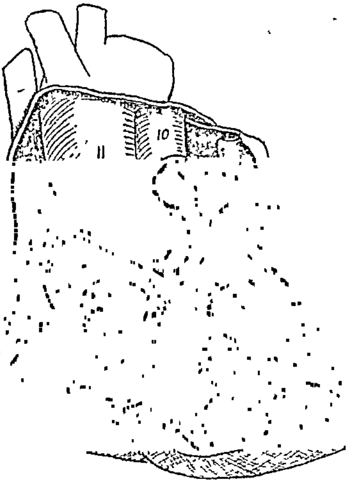
BY ARTHUR KEITH, M.D. ABERD.,
F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND CONSERVATOR OF THE MUSEUM.

LECTURE III.[1]

Delivered on March 12th.

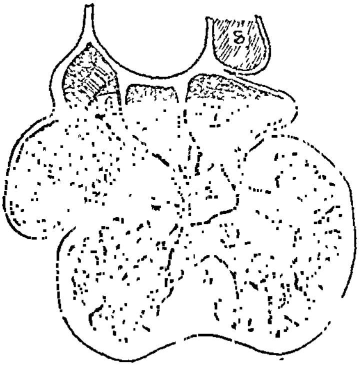
Absence of the septum ovale.—The condition I now proceed to describe to you, although frequently regarded as patency of the foramen ovale, is really a more serious defect. The malformation is shown in Fig. 19; we have no specimen in the College collection and I have seen only five examples. Not only is the foramen ovale open, but the septum ovale—that part of the interauricular septum which forms the floor of the fossa ovalis—is absent, so that there is a large circular window between the two auricles. The lower margin of the orifice is formed by a septal strand which can be traced to the valves bounding the orifice of the coronary sinus, which it will be remembered are derivatives of the first chamber of the heart—the sinus venosus. The condition is interesting because it bears out the statement made by His, and afterwards denied by Born, that in the lowest part of the interauricular septum there is an element derived from the sinus venosus (Fig. 20). It is also important because the node or small mass of peculiar muscle in which the auriculo-ventricular bundle commences is found in the region of the interauricular septum formed by the sinus element. Indeed, Retzer regards the node as really composed of sinus musculature and the bundle and its branches as outgrowth from the node—a view which is not only in opposition to all that is known of the comparative anatomy of the bundle, but also unsupported by embryological evidence. In cases of absence of the septum ovale the element derived from the sinus and described by His under the name of spini vestibuli is present, while the real interauricular septum, at least the part which forms the septum ovale, is absent. In a model prepared by His the spini vestibuli grows out from the lower fornix of the venous valves which guard the orifice of the sinus venosus, and reaches the endocardial cushions to fuse with the lower margin of the real interauricular septum, known to embryologists as the septum primum (Fig. 20). In reptilian hearts the lower fornix of the venous valves ends on the auriculo-ventricular valves (see Fig. 2 in THE LANCET, Feb. 27th, 1904, p. 556).

FIG. 19.



opening of inferior vena cava.

FIG. 20.



Coronal section of the heart of a human embryo about five weeks old. (After His). 1, Lower end of interauricular septum; 2, separation between auriculo-ventricular orifices formed out of the endocardial cushions—it is joined by the venous valves on the right side; 3, interventricular septum within ventricle; 4, the same on section; 5, opening of sinus venosus between right and left venous valves; 6, right auricle; 7, left auricle; 8, left superior vena cava; 9, infundibulum; *a*, *b*, lower ends of infundibular septum.

Abnormal foramen in posterior part of the interauricular septum.—There is another defect of the auricular septum of which I have seen but two examples: one of them occurred in the case of a woman, aged 45 years, under the care of Dr. F. J. Smith in the London Hospital. The defect, a large aperture, 15 by 20 millimetres, situated in the auricular septum above the fossa ovalis (Fig. 19), gave rise to no symptoms during life. In this case the defect was correlated with an abnormal termination of the right pulmonary veins; they terminated in the right auricle between the openings of the upper and lower caval veins. The mixed blood of the right auricle had by means of the interauricular defect free access to the left auricle. The communication in this case is probably one between the parts of the right and left auricle formed out of the sinus venosus.

Premature closure of foramen ovale.—How far imperfect formation and premature closure of the foramen ovale is a factor in the causation of other congenital malformations of the heart I am not yet in a position to say, but I have observed in several cases that the opening and fossa were abnormally small.

Abnormal septum in left auricle.—Time does not permit me to deal with the various abnormalities of the Thebesian, Eustachian, and other remnants of the two venous valves in the right auricle. In THE LANCET of Feb. 27th, 1904, p. 556, I have figured a case where both valves persisted. I now pass on to another condition which is not yet represented in the College collection—viz., the presence of an abnormal septum in the left auricle. The three cases which I have seen are those already published by Professor T. Wardrop

---

[1] Lectures I. and II. were published in THE LANCET of August 7th (p. 359) and 14th (p. 433), 1909, respectively.

Griffith (two) and by Dr. H. D. Rolleston (one). The illustration is taken from a case well reported by Potter and Ranson in the *Journal of Anatomy and Physiology* (October, 1904, p. 69). The left auricle is imperfectly divided by the septum into two compartments, one of them receiving the pulmonary veins—the vestibular part, the other or body of the auricle communicating with the appendix as well as the vestibule (Fig. 21). The condition is interesting because it shows the dual composition of the left auricle, one part, the vestibule, being derived from the opening up of the common termination of the pulmonary veins, the other from the primitive auricle. The abnormal septum occurs at the line of fusion of these two elements. In Fig. 22 is represented a heart in which there has been an arrest of the expansion of the pulmonary sinus to form the vestibule of the left auricle. I have seen three hearts showing this arrested condition of the vestibule—all of them associated with other grave malformations. As in the case shown in Fig. 22, the left superior vena cava and left duct of Cuvier [illegible]

Interbulbar or [illegible] —Before describing the defects of the interventricular septum it is convenient to return again to the aortic end of the heart and to describe certain defects in the septum of the heart which are at present very imperfectly understood. The position in which such a defect occurs is shown in Fig. 19. The opening is seen to be situated in the septal wall of the infundibulum of the right ventricle, and to communicate with the left ventricle under the right coronary cusp, which forms the upper boundary of the opening. It is situated in that part of the heart which we have seen is derived from the bulbus cordis, and we are dealing here with a defect not really of the interventricular septum, but of the interbulbar. Rokitansky, in his classical monograph, represents exactly the condition seen in a specimen lately shown to me by Professor Wardrop Griffith, and in two others, one in the Museum of St. George's Hospital, and already described by Dr. Rolleston and another in the Museum of Guy's Hospital. In the heart figured in my first lecture (Fig. 2, THE LANCET, August 7th, p. 360) a fibrous raphe (the interbulbar raphe) is seen to descend on the inner wall of the infundibulum, stretching from the semilunar valves above to the interventricular orifice below. It is in this raphe that interbulbar foramina occur.

Even in the normal heart a trace of the interbulbar raphe may be seen (Fig. 23). On the septal wall of the infundibulum two great bands of musculature are seen to arise, and descend on the inner wall of the right ventricle—one towards the base of the ventricle, and therefore fitly termed the right or basal band, and another towards the apex of the right ventricle, and which may therefore be named the left or apical band. These bands take their fixed origin from the interbulbar raphe and orifices of the aorta and pulmonary artery and play an important part in emptying the ventricle. The interbulbar septum is laid down at first as an endocardial fold into which the two muscular bands just described push their origins.

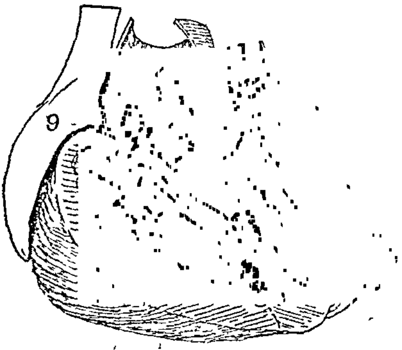
DEFECTS IN THE INTERVENTRICULAR SEPTUM.

1. *Interventricular* [illegible] The only malformation of the heart discussed by Hunter in his writings is that found in the heart of a boy in his fourteenth year whom he saw with Dr. Poultney. The heart showed a typical interventricular foramen associated with that conditon of pulmonary stenosis already described in these lectures as due to an arrest in the development of the infundibulum of the right ventricle. In the majority of such cases (85-90 per cent.) an interventricular foramen is present. Hunter regarded the obstruction at the entrance to the pulmonary artery as the cause of

the interventricular foramen; Meckel, on the other hand, regarded the fora [illegible] as a sequence. [illegible] which of these tw [illegible] to Hunter's sugge [illegible]

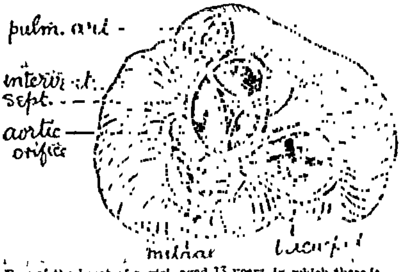
The boundarie [illegible] foramen are shown in a heart represented in Figs. 24 and 25. The right ventricle and atrophied infundibulum below the pulmonary artery are laid open in Fig. 24. The lower margin of the foramen is formed by the interventricular septum; the posterior boundary is formed by a band of fibrous tissue which is situated just below the non-coronary cusp of the aorta and derived from the mass of fibrous tissue formed out of the endocardial cushions. The upper boundary, cut across [illegible] of the aorta, is formed by [illegible] while the anterior margin [illegible] ptum. Thus the interventricular foramen extends along the upper margin of the interventricular septum from the interbulbar septum in front to the intervalvular or auriculo-ventricular septum, formed out of the endocardial cushions, behind. Its size is extremely variable; usually it is about 8 × 12 millimetres, but it may be little more than a pinhole or large enough to take [illegible] quence of events [illegible] interventricular [illegible] that the foramen [illegible] s become opened [illegible] very early in the [illegible] that its closure *depends on the full development of the infundibulum.* [illegible] om, an examination of the heart in [illegible] of the bulbus cavity to form the [illegible] most important part in its closure. [illegible] "4" marks the right infundibular [illegible] ings from the interbulbar septum. It will be apparent that as the infundibulum expands this great band of musculature is thrown across and helps to occlude the interventricular foramen. The occlusion is completed by the fusion of the endocardial cushion which lines the margin of the foramen. The tissue of this endocardial cushion forms the substance of the pars membranacea septi—the curtain which closes the interventricular foramen.

FIG. 24.



Heart of a boy, aged six years, with right ventricle and aorta [illegible] 8, left ventricle, 9, right auricle.

FIG 25.



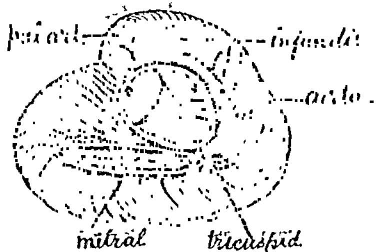
Base of the heart of a girl, aged 13 years, in which there is arrest of the infundibulum with large interventricular foramen. The position of the aortic valves is shown and the subdivision of the aortic orifice by the upper margin of the interventricular septum.

The effect of an interventricular foramen on the action of the heart.—The functional significance of an interventricular foramen is best realised by such a view of the heart as is represented in Fig. 25. It is from the heart of a girl, aged 13 [illegible] partially opened up. [illegible] septum is seen to [illegible] ne-third of it being in communication with the right ventricle, two-thirds with the left. The body of the right ventricle discharged its blood by two orifices: (1) a small part into the constricted infundibulum; and (2) a much larger part into the aorta. The walls of the body of the ventricle are hypertrophied so as to be able to compete on equal terms with the left ventricle *in supplying the body with blood.*

It is difficult to account for those comparatively rare cases where an interventricular foramen is present, yet the hearts seem otherwise perfectly formed. I have seen nine hearts of this kind. In all the foramen was of comparatively small size and had a membranous margin. The theory I have advanced, that the expansion of the infundibulum leads to the closure of the interventricular foramen, will not account for these cases. This class of hearts requires further study.

Irregular interventricular foramina.—Amongst the specimens examined for the purpose of these lectures there were four in wh [illegible] by irregular [illegible] inal muscular [illegible] ned unobliterated (Fig. 19).

FIG. 26.



Base of a heart in which there are (1) stenosis of the right auriculo-ventricular opening; (2) suppression of the body of the right ventricle, and (3) development of the infundibulum of the right ventricle. The common ventricle is really the left; the auriculo-ventricular bundle is seen on the right lateral wall of the ventricle.

Atrophy of left auricle.—The older writers on malformation in the heart endeavoured to utilise the classification *employed in comparative anatomy and* divide abnormal hearts into two-chambered and three-chambered hearts. A two-chambered human heart I have never seen; in three hearts of stillborn children, where there was complete stenosis of the mitral orifice, the left auricle was so small that it might easily have escaped detection; I have never seen the interauricular septum completely absent.

Hearts with one ventricle.—Amongst the malformed hearts which are said to have a common ventricle there are really three kinds: (1) those in which the interventricular septum is so little developed, or, to put it differently, the interventricular foramen is so large that the two ventricles are rightly said to form one char [illegible] the right ventricle is suppressed [illegible] to the right side of the heart; [illegible] left ventricle is suppressed by [illegible] the left wall of

The murmurs that develop during an attack of rheumatism are usually confined to the mitral area when there has been no previous valvular disease. In relation to the cardiac rhythm they are, first, a late diastolic murmur, and, secondly, a systolic murmur. These two bruits, as a rule, do not occur together and the diastolic is often replaced by a systolic in the later stages of an attack. They are both temporary murmurs, although the systolic may last until the development of a permanent systolic bruit due to deformity of the mitral valve from contraction after valvulitis. Neither of these murmurs can be explained by an active inflammation of the valve, since there is no reason why this should hamper the functions of the valve in any way. Personally, I consider that Dr. Coombs's explanation of the mode of production of these murmurs is in the main correct, but I differ from him in certain details.

Taking first the systolic bruit, its position and character are those of a murmur due to a regurgitation through the mitral valve. An inflammation of the cusps of the valve could not render it incompetent until the cusps were deformed by the subsequent contraction, and this systolic murmur is often one of the earliest phenomena of rheumatism. Dilatation of the left ventricle may lead to incompetence of the valve, but considerable dilatation is often found without a murmur, and even in rheumatism a murmur often develops, while there is but little dilatation. Hence, as Dr. Coombs rightly insists, the murmur must be caused by widening of the orifice by myocardial atony, and this is confirmed by the enlargement of the mitral ring that is found post mortem. To make this statement is, however, not sufficient: an explanation is required as to how such a widening is anatomically and pathologically possible. The cardiac openings are surrounded by fibrous rings and are closed completely by the cusps of the valves, provided the openings are sufficiently small. The pulmonary and aortic orifices do not vary much in size, but the tricuspid and the mitral can vary to a very considerable extent. The reason for this is that there is, besides the fibrous ring, a band of circularly disposed muscle fibres around each of the auriculo-ventricular openings and each of these orifices is dependent for its size on the tone of the circular muscle. The size, of course, increases with loss of tone and diminishes with increase of tone. It is by no means necessary that the tone of these muscle rings should be in exactly the same condition as the rest of the cardiac muscle; in fact, under normal conditions tone is probably greater here than elsewhere. The sphincters of the valves, if one may call them so, may also have their tone altered apart from the general cardiac muscle—e.g., by the action of nervous influences. The valvular cusps are so arranged that they can still meet and close the mitral opening with a moderate widening, so that considerable dilatation of the left ventricle may take place without incompetence of the valve. The capacity of the ventricle, too, increases in dilatation more rapidly than the area of its walls, so that a decided increase of the [illegible] icle would be associated with a very [illegible] tral orifice.

[illegible] arrangements it is evident that the main factor in the production of mitral incompetence early in rheumatism is a loss of tone in the mitral sphincter. Are there any pathological reasons for a loss of tone in this sphincter as apart from a general alteration of muscle tone? We are informed that in rheumatism inflammatory nodules tend to develop, especially near the mitral ring and near the root of the aorta. In such nodules toxins would be elaborated (whether formic acid or others) and the lymph of the part would contain these toxins. Hence the muscle fibres of the mitral sphincter would be bathed in toxins, the special action of which is to diminish tonicity, while the rest of the cardiac muscle would be much less severely poisoned since the toxins must be absorbed into the general circulation in order to reach any fibres that are not in close proximity to the nodules. Thus in any rheumatic myocarditis an early loss of tone in the sphincter of the mitral valve would be expected with the development of a regurgitant murmur. Nodules tend also to be formed near the root of the aorta; but the aorta has no sphincter and so no change is produced in the size of the aortic opening by the local inflammation.

The other murmur that is produced during an attack of rheumatic fever is also heard at the apex but is diastolic in time. This murmur is soft and blowing in character, and has not the rough crescendo quality of the bruit of mitral stenosis. It could hardly be caused by the minute vegetations that are found on the valve post mortem, while the hypothesis that the valvular cusps become stiffened and so obstruct the blood has very little evidence in its support. The murmur is only temporary and seems to have nothing to do with the development of a genuine stenosis of the valve. A similar murmur may, however, be heard in mitral stenosis, especially in the later stages, when the left auricle fails in its duty of driving blood into the ventricle. In mitral stenosis this murmur is almost certainly due to the aspiration of blood from the auricle through the constricted mitral by the dilating ventricle. The suggestion of Dr. Coombs, that the diastolic murmur of rheumatism is due to the same cause, seems to me to be a sound one. The dilatation of the ventricle produced by the rheumatic poison would lead to a comparative narrowing of the mitral valve, since this is not stretched in proportion to the increase of the ventricular capacity, provided that the tone of the mitral sphincter is not specially damaged. The aspiration of the dilated ventricle through this comparatively narrow orifice would cause the bruit. The aspirating power of the dilating ventricle depends on the strength of its preceding contraction or, in other words, on the contractility of the muscle. The contractility is often damaged in rheumatism but not to the same extent as the tonicity, and the two properties are not affected in proportion to one another. Thus in a case of rheumatic dilatation of the heart it will depend on the extent of the damage to the contractility whether the diastolic bruit is heard or not. This conclusion, founded on theoretical considerations, accords with my vague recollections of clinical cases, but the point requires extended study at the bedside. It is of interest that a diastolic murmur does not develop in the dilatation of the heart in diphtheria; the diphtheritic poison mainly attacks contractility and only to a lesser extent tonicity.

While being convinced that the diastolic murmur is produced in the manner here described I cannot agree that the murmur has anything to do with inflammation of the cardiac muscle. Indeed, I should take it as a sign that myocarditis was absent and that there was merely poisoning of the muscle fibres. I have explained how myocarditis would be expected to result in a loss of tone in the mitral sphincter. Such a loss of tone, even if insufficient to cause a systolic murmur, would be quite enough to prevent a diastolic one from being developed, since the theoretical explanation of the latter presupposes a comparative stenosis of the mitral valve with dilatation of the ventricle.

Death in a first attack of [illegible] very uncommon apart from hyperpyrexia, but [illegible] may fatally affect a heart that [illegible] disease or pericardial adhesions [illegible] previously injured by poisoning [illegible] of rheumatic myocarditis are [illegible] to lead to a fatal issue, and the main factor in the production of a fatal cardiac failure seems to be action of the toxin on the muscle cells. In this respect rheumatism is like other specific diseases—for instance, diphtheria. In both diseases fatty infiltration of the muscle fibres has been described, but a poisoned cell need show n[illegible] change from the action of the poison, and the [illegible]ubt as to the pathological significance [illegible] It is evident that the action of the [illegible] severe than is the case with diphtheria. In rheumatism evidence of cardiac poisoning in the form of dilatation is very common, but death is very rare, while in diphtheria death is frequent when there is any dilatation to show that the heart is affected. The proba[illegible] of this is that the different poisons of [illegible]ct the several properties of the cardiac muscle to different extents, and that the poison of rheumatism mainly attacks the tonicity, while that of diphtheria specially implicates the contractility.

In conclusion, it may be emphasised that, while pericarditis gives the usual well-recognised signs of its presence, recent endocarditis causes no physical signs whatever. Affections of the myocardium in [illegible] may be divided into the inflammatory and the [illegible]y lesions cause a loss of tone in the mus[illegible] the mitral valve allowing of mitral regurgitation. Thus an apical systolic murmur is the sign of rheumatic myocarditis, and is, indeed, the only sign of inflammation of the heart apart from pericarditis. In the majority of cases the presence of such a systolic bruit is diagnostic of myocarditis, but in a small minority a regurgitant murmur may result from general dilatation without any inflammation. Poisoning of the heart muscle in rheumatism causes a general dilatation of the heart and sometimes a mitral diastolic murmur. Dilatation may or may not be associated with inflammation of the myocardium, but the diastolic murmur may be taken to imply an absence of myocarditis at the time it is heard. As far as the immediate welfare of the patient is concerned the toxic action of rheumatism is more important than the inflammatory, since it is to the consequent failure of tonicity and contractility that death during an attack is due. For his future welfare the inflammatory lesions become of chief account. Myocarditis is probably always associated with endocarditis, so that there is danger of permanent damage to a valve and the inflammation in the muscle itself may lead to such local damage *that tone is never regained, leaving a permanent* widening of the orifice. It is probable that the muscle may sometimes completely recover both from the poisoning and the inflammation, but in other cases the muscle never again becomes healthy after their disappearance. Such occasional permanent damage to the muscle by the toxin would explain the different behaviour of different hearts after rheumatism. In some hypertrophy readily takes place and there is a ready compensation for valvular lesion, whilst others rapidly fail. Again, some hearts respond readily to drugs like digitalis, whilst others are feebly, or not at all, affected.

It would appear from the foregoing considerations that there has been a tendency to exaggerate the importance of myocarditis in rheumatism. The more pressing danger [illegible] responsible for the only physical sign of cardiac inflammation apart from pericarditis, and cardiac inflammation is the cause of post-rheumatic valvular disease. It is probable, too, that the inflammation in the muscle assists to some extent in the production of a permanent incompetency of the mitral valve, and may also, in association with the toxin, be of account in permanently damaging the muscle, so that it may fail to "compensate" for valvular lesions and not be healthy enough to respond to the action of drugs.

Upper Berkeley-street, W.

FIVE CASES OF TUMOUR OF THE LARGE INTESTINE SIMULATING DISEASE OF THE UTERUS OR UTERINE APPENDAGES.

BY VICTOR BONNEY, M.S., M.D., B.SC. LOND.,
F.R.C.S. ENG., M.R.C.P. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL,
SENIOR SURGEON TO OUT PATIENTS TO THE CHELSEA
HOSPITAL FOR WOMEN.

THE following cases illustrate how closely tumours of the large intestine in women may simulate disease of the uterus or its appendages.

CASE 1. *Inflammatory tumour of the cæcum simulating a uterine myoma.*—Two years ago I assisted Dr. William Duncan to operate on an elderly lady who presented a large abdominal tumour centrally placed, defined in outline, solid to the touch, and dull on percussion. On vaginal examination it appeared to be attached to the top of the uterus and to be continuous with it. The principal feature of the case was the tumour, which had existed for a considerable time. Pain was complained of also. No menstrual symptoms were present but the patient had passed the climacteric. The general appearance and feel of the mass suggested strongly [illegible] species of degeneration. [illegible] middle line the mass was [illegible] of a "cake" of much- [illegible] losely adherent in front to [illegible] at its lower part to the top [illegible] Several small collections [illegible] and the abdominal wall. When the omentum had been separated with considerable difficulty it was found that the underlying portion of the tumour was composed of the cæcum and terminal four inches of the ileum. The wall of the bowel was enormously [illegible] were firmly conjoined [illegible] of malignant disease [illegible] the involved intestine having been separated I assisted Dr. Duncan to resect the whole cæcum together with five inches of the adjacent ileum. The lower end of the ascending colon was closed and the cut end of the small intestine was implanted into its inner side, about one inch above the point of occlusion.

The patient subsequently developed a fæcal fistula with much suppuration in the wound, but eventually recovered and is at the present time, I understand, in very good health.

Microscopical investigation of the parts removed showed that the condition was solely due to an immense inflammatory sclerotic thickening of the intestinal wall. The *appendix appeared to have been merged in the general* tumour, at all events it could not be separately defined. The origin of the condition was therefore not determinable.

CASE 2. [illegible] Chelsea Hospital for Women last September, giving a history of abdominal pain and wasting for the last four months. The bowels had been very constipated and much pain on micturition was complained of. On examination the abdomen was much distended by an irregular mass of variable consistency occupying its lower left quadrant. The flanks were dull and there was evidence of a considerable quantity of free fluid in the abdominal cavity. On vaginal examination the mass could be felt apparently arising from the region of the left ovary.

I made a median subumbilical incision, and on opening the peritoneum a quantity of ascitic fluid escaped. A mass of adherent omentum then presented which was attached at its lower part to the back of the uterus and left broad ligament. When this had been separated it was found to screen a tumour in the pelvis of considerable size, which was composed of adherent portions of the transverse colon and sigmoid flexure. On closer investigation it was seen to be due to a primary carcinoma of the middle of the transverse colon which had "sagged down" into the pelvis, adhered to the sigmoid flexure, infiltrated it, and perforated into it so that on separating the two pieces of gut a hole was left in either portion at the site of the short circuiting. I therefore first resected the diseased portion of the transverse colon and performed an end-to-end anastomosis of the cut ends and then similarly treated the infiltrated portion of [illegible]

This patient made [illegible] the present time is [illegible] the operation, and without any sign of recurrence. The growth was proved to be a columnar-celled carcinoma.

CASE 3. *Carcinoma of the sigmoid colon simulating an ovarian dermoid cyst.*—On the same afternoon in which I operated on the foregoing case, and also at the Chelsea Hospital for Women, I opened the abdomen of a patient, aged 27 years, who presented a rounded, centrally placed tumour rising midway between the pubes and umbilicus, and situated in front of the uterus and between it and the bladder. Her history was one of severe pain on micturition and pain in the back extending over three months. She had had occasional attacks of diarrhœa. The rounded contour, the position of the tumour, its semi-solid consistency, and the age of the patient caused a pre-operative diagnosis of dermoid cyst of the ovary to be made.

I made a central incision over the tumour and found it to consist superficially of adherent thickened omentum, under and conjoined with which was a loop of the sigmoid colon containing a large annular growth. The bowel above the structure was much thickened and distended with fæcal masses. The whole mass lay between the uterus and bladder, filling up the utero-vesical pouch and was very adherent, especially to the bladder. Having freed the bowel and cut off the diseased omentum I resected some eight inches of the bowel, including the growth, and per- [illegible] anastomosis having previously expressed [illegible] cal accumulation that it con-

The patient made an uninterrupted recovery. The growth proved to be a columnar-celled carcinoma.

CASE 4. *Carcinoma of the sigmoid simulating disease of the right uterine appendage.*—This case I also operated upon at the Chelsea Hospital for Women in September, 1908. Her age was 31 years, and her symptoms, which consisted of pain in the lower abdomen and back, had existed for three months. For the first two months of this period she had had frequent attacks of diarrhœa, but for the last month this had ceased and she had become very constipated. On abdominal examination there were tenderness and an ill-defined sense of swelling to the right of the middle line, and low down in the pelvis per vaginam a well-marked mass could be felt filling the right half of the pelvis and pushing the uterus forwards and to the left. A provisional diagnosis of inflammatory disease of the right ovary and tube was made.

When I opened the abdomen I found the tumour to consist of a loop of sigmoid colon at the flexure of which a large annular growth was situated. This was matted over with adherent small intestine and omentum and the whole conglomerate mass was attached to the back of the right broad ligament and the right lateral pelvic wall. The ovary and tube on either side were normal. Having separated the diseased intestine and removed the omentum, I resected the whole loop containing the growth together with some enlarged glands. The upper end of the bowel was then emptied of a large quantity of retained scybalæ and an end-to-end anastomosis was performed.

This patient also made an excellent recovery. The growth proved to be a columnar-celled carcinoma. At the present time the patient is quite well, I believe.

CASE 5. *Carcinoma of the sigmoid with secondary growth in the anterior rectal wall simulating a malignant ovarian tumour.*—In 1909 a patient aged 54 years was admitted into the Middlesex Hospital under my care as a case of malignant ovarian tumour. She was a miserably emaciated-looking woman with a degree of general abdominal distension but with no defined tumour to be felt from above. On vaginal examination a large mass lay between the back of the uterus and the front of the rectum and was apparently adherent to both. On rectal examination the tumour could be felt pressing on to the anterior rectal wall, which it had evidently superficially involved, but the mucosa of the bowel was unaffected. The history of the case was one of abdominal and pelvic pain for some months. For the last three weeks she had had diarrhœa.

I opened the abdomen in the middle line and found that the tumour was screened by a quantity of adherent omentum. It was apparently springing from the back of the right broad ligament, and I thought at first that I was dealing with some tumour of the ovary belonging to that side. I began to separate it, when a quantity of fæcal matter escaped into the pelvis and proclaimed the mass to be connected with the intestine. On separating it into its constituent parts and removing the diseased omentum I found it to be a large carcinomatous mass in the upper part of the sigmoid colon which had gravitated into the pouch of Douglas and then adhered to the anterior rectal wall which it had begun to infiltrate. I had torn through this mass while separating it from the rectum. I therefore resected the entire sigmoid colon, together with the upper part of the rectum, so as to include both areas of disease. Fortunately, owing to the extremely relaxed condition of the patient's mesenteries, I was able to pull the lower end of the descending colon down to the bottom of Douglas's pouch, and, obtaining sufficient free margin of the upper end of the cut rectum by freeing it from its peritoneal connexions and pulling it up, I was able to effect an end-to-end anastomosis. Before doing so, I emptied, as before, the colon of its retained fæcal matter, and as a considerable quantity of fæces had escaped into the pelvis owing to my tearing through the growth when separating it, the pelvis was carefully washed out with saline solution before I closed the abdominal wound.

The patient had a somewhat prolonged convalescence. The abdominal wound suppurated badly, but the line of anastomosis remained watertight although for some time she had a fæculo-purulent discharge from the anus. She left the hospital eventually in a very satisfactory state. The growth was proved to be a columnar-celled carcinoma.

These five cases are instructive from several points of view. The effect of gravity on tumours of the large intestine is seen to be very marked. In all of these patients the tumour mass had caused the affected portion of bowel to gravitate downwards into the pelvis, to certain of the structures contained in which it had subsequently adhered. In Cases 2 and 5 this adhesion had occurred between the diseased bowel and the healthy bowel below it. In Case 2 actual short-circuiting had taken place and in Case 5 was about to take place. In Case 1 adhesion had occurred to the top of the uterus, in Case 3 to the front of the uterus and bladder, and in Case 4 to the back of the right broad ligament. It is therefore apparent that in growths of the large intestine one must not expect to find the position of the tumour necessarily corresponding with the normal anatomical position of the portion of gut involved, and that it is not safe to exclude from the diagnosis any portion of the large intestine merely on account of the position of the mass to be felt.

Another important fact illustrated by these cases is the large size of the palpable mass that may be produced as a result of a growth of the wall of the large intestine. This mass is a *conglomerate*—i.e., it is made up of several constituents. First amongst these is the omentum, which early becomes adherent and thickened. This is augmented by fusion of the primary growth with neighbouring coils of gut, swollen appendices epiploicæ, the uterine appendages or the uterus itself. Finally, the whole becomes rounded off by collections of organised peritoneal exudate, and the result is a tumour of large dimensions of which the primary disease forms but a small part.

When such a mass occupies the pelvis the simulation of disease of the uterus or uterine appendages may be, as these cases show, very close indeed, especially in the absence of symptoms pointing strongly to the bowel. Slight intestinal symptoms, such as moderate diarrhœa or constipation, are so commonly met with in *bonâ-fide* disease of the female genital organs as to be of little value in the differential diagnosis.

It will be seen that in four out of the five cases end-to-end anastomosis was performed (in Case 2 in two places). I am aware that certain authorities favour lateral anastomosis in the case of the large intestine on account of the larger aperture of communication that can be effected between the anastomosed segments of the bowel. End-to-end union has, however, in my hands proved very satisfactory. It certainly has the advantage over lateral junction of reducing the suture line to its smallest limit and in the large intestine, where so free an anastomosis exists between the vessels of the meso-colon, the danger of anæmic necrosis of the sutured ends is very slight.

I have always used three layers of sutures: the first, a continuous suture through mucosa and muscle; the second, a continuous suture through muscle and peritoneum; and the third, a series of interrupted Lembert sutures picking up the peritoneum only. No doubt this involves the inturning of a considerable portion of the bowel wall, much of which subsequently sloughs off, but this is of small importance compared with rendering the line of junction watertight. I attach great importance to the emptying of the upper bowel before performing the anastomosis. It may be objected that this proceeding increases the risk of infecting the operation area, but I am of opinion that healthy fæcal matter, at all events, is very slightly septic, and that if the parts exposed by the incision are carefully packed off with sterilised gauze before the process and the bowel end thoroughly washed with saline solution after it, it may be carried out with great advantage to the patient.

Harley-street, W.

A CASE OF HENOCH'S PURPURA ASSOCIATED WITH ANGIONEUROTIC ŒDEMA.

BY ALEXANDER DON, M.A., M.B., C.M. ABERD.,
F.R.C.S. EDIN.,
SURGEON TO, AND LECTURER ON CLINICAL SURGERY AT, THE ROYAL INFIRMARY, DUNDEE.

A BOY, aged 8½ years, whom I saw on Feb. 8th, 1908, had been ailing for over a fortnight, but had always been able to be at school. His appetite had been very good, but he had swelling of the left knee and ankle and dysentery. A week previously there had been a swelling over the dorsum of the right foot. The left knee next became *painful*, and on examination his mother found that it was swollen. The elbow then became sore. This was his condition when I first saw him. The knee and elbow contained fluid. The skin around both looked as if bruised, and on different parts of the body were what seemed like old bruises, especially a mark over the right trochanter major. Closer examination showed that many of these were really subcutaneous hæmorrhages. The patches varied in size from sixpenny-pieces to half-crowns, were irregular in outline, and were in all stages of absorption, some being bright red, others darker, and some only little more than a greenish-yellow stain. Other spots resembled fleabites and did not show the changes mentioned as they faded. One of these was on the right cheek, and others over the trunk below the umbilicus and on both legs, feet, and arms. These spots were distinctly worse on the legs and forearms. There had been diarrhœa for a week, foul-smelling and dysenteric—i.e., containing blood and mucus. There was no pain in the abdomen. The temperature was 99° F. and the pulse was 100 per minute. There was no cardiac symptom nor albumin. He was put on powders, one four-hourly, containing calomel ½ gr., salol 2 gr., and pulv. ipecac. 1 gr. Next day, the 9th, the penis was œdematous with [illegible] It was quite free from pain and [illegible] at the trunk. The knee was [illegible] good deal. There were some [illegible] 10th the whole scrotum was livid red and œdematous, but the point of the penis was less swollen. The elbow was quite better, but there was a good deal of greenish-yellow staining down the forearm. The right hip had several erythematous patches, raised up like true urticaria, but not itchy. The diarrhœa was less frequent. The temperature was 99·6° and the pulse was 100. A sample of fæces was taken for examination. Professor Sutherland reported on this as follows:—

> A. Films made directly from the specimen are examined in the [illegible] after fixing with corrosive [illegible] and eosin. Films are also [illegible]sin, and by Gram's method. The following organisms are [illegible]

The œdema gradually disappeared from the penis and [illegible] The knee and elbow on the [illegible] began to rise on the front of [illegible] on firm pressure. There was [illegible] œdema. On Feb. 12th the fæces were again sent for examination, and the report is as *follows*:—

> A. An examination similar to the last is made No amœbæ are found. The organisms are less abundant. B. coli is present in distinctly smaller numbers The larger Gram positive bacillus is only present in very small amount. The majority of organisms are cocci—often in long chains Examination for tubercle bacillus is again negative. B. Abundant growths are obtained on agar of the large Gram-positive bacillus The B. coli and the cocci are apparently overgrown. The larger number of fatty catarrhal cells, the abundance of red blood corpuscles, and the scantiness of leucocytes in the material point in the direction of an extensive catarrhal rather than suppurative inflammation of the intestinal tract.

The patch in front of the right elbow increased in size during the next few days and then faded, leaving a greenish-yellow stain. There was great pain of a colicky nature over the descending colon, and a firm sausage-shaped tumour could be made out on palpation, though the patient winced a little and fixed the abdominal muscles on that side. The left knee and elbow were now painlessly moveable. No new hæmorrhages or swellings had appeared. Next morning, the 13th, he was a good deal better, but there was still pain along the descending colon which was less distinctly palpable. There had been no movement of the bowels. After my visit I heard by telephone that he had had a bad attack of diarrhœa with vomiting. He vomited twice, the second time quite green material. The bowels moved almost continuously, 13 or 14 times, and latterly pure blood with great tenesmus. After the last motion he was quite exhausted and dropped off to sleep. I ordered Dover's powder two grains. He slept again after the first dose. His milk was now peptonised. On the 14th he was better, the temperature and pulse being normal. The scrotum was now quite normal except at its most dependent part, where a little œdema still persisted. The only motion was of the muco-sanguineous type, with a good deal of pea-soupy fæces. There had been slight hæmorrhage from the nose. On the 15th the dorsum of the right foot and the ankle were œdematous and pitted on pressure. There was no pain anywhere and he was quite cheerful. On the 16th the right foot was pretty much as before. He complained very much of his back and on examination I found a new œdematous patch right over the centre of the lowest dorsal spines, which were very painful to touch. There had also been some swelling of the right ear, but it had almost disappeared, only a little remaining at the junction of the pinna with the head above. There was a little blood in the stool last night. He seemed much lower to-day. His pulse was feeble and about 130 per minute, but there was no fever. On the 17th [illegible] 96. The patient [illegible] There was no mo[illegible] of the abdomen. The right knee was distended with fluid and the œdema extended up from the foot to the knee. The foot was not now swollen. The patch on the head had spread over the temporal bone, and was well defined and painful to touch. The swelling on the back was just about the same. On the 18th the knee was less painful, and the œdema was up as far as the middle third of the thigh. The greatest change was in the head. What was a small patch of the size of the palm over the right temporal ridge had spread all over the top of the head and down to the other ear, closing the right eye, and down to the supra-orbital ridge of the left. It was only slightly painful now to touch. The pulse was 110 and rather feeble. The heart sounds were quite closed in all areas, but not strong. The back had resumed its normal outline. The bowels had operated four times, once with a little blood. He felt quite comfortable, but was drowsy. On the 19th the pulse was 84 and the temperature was 99°. The swelling of the head had quite changed from where it was on the 18th. The right eye was open, and the left now closed. The swelling had travelled down the back of the head to the neck, and down the face on the right side to the ear, and on the left side to the zygoma. There were a few new spots of purpura over the legs about the knee-joints. The heart gave a slight systolic bruit over the apex. On the 20th the face was still swollen, especially over the cheeks and downwards. The right knee could now be bent slightly. The motions were dark, pea-soupy, with a little blood. He was very hungry. The pulse was still rapid. On the 21st he was much better. There was practically no swelling anywhere except on the left cheek at the angle of the lower jaw. He was feeling very well. The pulse was about 60 per minute, rather irregular, and intermittent. He had only one motion and it was more normal. The right leg was quite better. On the 23rd the stools were formed. The patient was very hungry. He was allowed a little ground rice and jelly. There was still a slight systolic murmur. The urine was very much clearer and there was no albumin. On the 25th the patient was improving. There was some dysentery yesterday, but it has ceased. There was no complaint of any kind except hunger. The improvement continued and he was able to sit up a little by the end of the month. He was advised to continue calomel and salol as disinfectants to the bowel and to prevent recurrence. This he did, and though he has at times felt out of sorts and bilious there has been no outbreak of the old symptoms during the last 14 months.

His personal history contains nothing of importance bearing on his symptoms. He was born in Australia. He had been subject to attacks of biliousness and was operated on for enlarged tonsils two and a half years ago. He was also circumcised, and at that time had an erysipelatous rash all over his body and was seriously ill. He had just then recovered from measles. His father and mother are alive and healthy. There was no history of any blood disease on either side.

This is the second case of angioneurotic œdema associated with purpura which I have met with, the first case[1] being less marked in its distribution and severity. The coexistence of these two symptoms, for one can hardly class them as distinct diseases, is mentioned by Butler,[2] and Osler[3] thinks that both may depend on "some poison—an alkaloid—possibly the result of some faulty chylopoietic metabolism, which in varying doses in different constitutions excites in one urticaria, in a second peliosis rheumatica, and in a third in the lumbar region, sensation of dragging in the rectum, and pain and straining at stool. The bowels never acted without purgatives. Examination of the rectum disclosed a firm thick band high up in the bowel. The patient gave a history of frequent attacks of diarrhœa with blood 10 years ago. There was no history of syphilis. More than six months ago she underwent an operation for external and internal hæmorrhoids without relief to the symptoms. Dilatation of the stricture had been done twice a week and this caused much pain but gave no relief. After treatment for four weeks by injections of fibrolysin every second day and occasional passage of a dilator the bowels have acted naturally without drugs, pain and discomfort have disappeared, and the instrument does not cause much inconvenience. The patient has gained weight and now describes living as a pleasure.

CASE 3. *Dupuytren's contraction.*—A man, aged 64 years, had had contraction of the palmar fascia in both hands for 20 years. The contraction was so marked in the right hand that the index and middle fingers were fixed closely to the palm and a pen handle could be with difficulty passed between the contracted fingers and the palmar surface. The bands of fascia stood up as hard, tight cords which were quite inelastic. Treatment three times a week resulted in softening of the hands and some elasticity being imparted to the cords. Passive movement and massage were also employed, and after 30 injections he can now extend and flex the fingers almost to the normal extent and the stiffness and swelling of the hands have disappeared, while the fascial bands have become soft and elastic.

CASE 3. *Chronic rheumatoid arthritis.*—A married woman, aged 47 years, for several years had suffered from this complaint. She was unable to stand on account of the pains in the knees, which could not be flexed without pain, and grating and swelling were marked. She had been practically bedridden for 12 months prior to the treatment. Various remedies and methods had been employed with slight temporary relief. After 12 injections the pain was much lessened and creaking and swelling disappeared, while the knees could be flexed voluntarily. After 30 injections had been given the pains also disappeared and she was able to walk about her room without artificial aid. She had previously used crutches for a fortnight. Her general condition was much improved. During the last five weeks treatment has been given once a week and she now can walk slowly with little discomfort, and she states that each day she feels herself becoming stronger in the knees.

CASE 4. *Stricture of the urethra.*—A man, aged 46 years, had suffered from double stricture for 20 years. Eight years ago urethrotomy had been performed without good result. False passages had been made by catheterisations and cicatrices could be easily felt. No. 5 (English) with difficulty was passed through the smaller stricture. Injections of fibrolysin were given twice a week and gradual dilatation was practised. The anterior stricture allowed passage of No. 12 at the end of three weeks, and two weeks later No. 12 was passed through both strictures Frequency of micturition has been relieved and the patient has gained 12 pounds in weight. This patient had been treated energetically for syphilitic orchitis for some months ten years ago without avail, and one testicle had been removed. At the beginning of treatment by fibrolysin there was a nodular gummatous swelling in the remaining testicle. This became soft and has now almost disappeared.

CASE 5. *Gastric adhesion.*—A married woman, aged 29 years, suffered for five years from vomiting and pains in the left hypochondrium. She was anæmic and had vomited blood on several occasions. A large meal increased the pain and movements like stretching or reaching caused pain in the left side. Examination of the gastric contents gave slight hyperchlorhydria. Treatment by fibrolysin injections and massage of the stomach after a bulky meal for three weeks resulted in disappearance of the pains with increase in appetite and improvement in the anæmic condition.

CASE 6. *Fibrous adhesions of the knee-joint.*—A man, aged 29 years, had gonorrhœa nine months before, complicated by synovitis of the right knee, which remained stiff, painful, and swollen. Massage, hot air, and general treatment had no good effect. Fibrolysin was injected for two months and massage and passive movements were applied to the joint. The thickening round the joint became lessened and movement has been restored, though the knee cannot yet be fully flexed. Pain disappeared after six injections.

From the foregoing it will be seen that fibrolysin is apparently indicated in any pathological state having fibrosis as its basis. The softening of the fibrous tissue allows of manipulation and stretching. The injection of the drug *of itself* will *not* result in local benefit in my opinion. It should be *supplemented* by massage and other physical measures. The remarkable general improvement in health in all cases is noteworthy, as well as the advantages which patients may derive in cases that have hitherto been regarded as hopeless. Absorption is fairly rapid after intramuscular injection in adults of middle age, and in one case, that of a man aged 77 years, the taste of the drug could be detected a quarter of an hour after injection. In this case, too, the skin became soft and pliable and the health much improved. Sufficient time has not elapsed to allow one to form an estimate of the permanency or otherwise of the good results obtained. In the case of urethral stricture so far there has been no tendency to recontraction. I purpose keeping cases under observation so that later a further communication may be made on the subject.

Melbourne.

AN UNUSUAL TYPE OF STOMATITIS IN AN INFANT.

BY A. H. BREHAUT, B.A., M.D., B.C. CANTAB.,
HONORARY MEDICAL OFFICER TO THE VICTORIA COTTAGE HOSPITAL, GUERNSEY.

THE following case of stomatitis occurring in an infant of four months presents unusual features and may be worth recording. Henoch in his lectures on Diseases of Children mentions two varieties of se [illegible] and gangrenous. The former is [illegible] with teething; the latter usually occurs as a sequel to one of the acute infectious diseases amidst unhygienic surroundings. In both cases the mucous membrane is first involved; sometimes the ulcerative type develops into the more severe, and usually fatal, gangrenous type.

In the present case the age of the patient—four months—is unusual; the severer types of stomatitis occur especially between the ages of two and 12 years.[1] Primary dentition had not as yet set in; there was no history of any acute infectious disease or of mercurialism; the surroundings were not such as to call for censure. The case occurred on a farm and there was no history of illness among the cattle.[2] The child was bottle-fed and had no evidence of rickets or scurvy; he was anæmic but was well grown and sturdy. The acute onset and [illegible] showed the infection, whatever its [illegible] and not constitutional in origin. [illegible] so placed as to be able to take cultures of any micro-organisms which may have been present.

The patient, aged four months, was seen on April 30th, 1908. The history as obtained was that on the previous day (the 29th) he had been ill or very bad tempered all day; in the evening it was noticed that the cheek was a little swollen; by the next morning (the 30th) this swelling had undergone considerable increase in size. On examination the left cheek was seen to be very swollen and the skin was shiny; the swelling was not localised. The cheek was very hard and tense, no pitting could be obtained, it was extremely tender, and a slight touch produced a shriek. The inside of the cheek was dusky, and about half-way back on a level with the alveolar border of the lower jaw there was a small patch of about the size of a No. 4 shot, dusky grey in colour, which had the appearance of threatening gangrene. There was no specific odour attached to the breath, but it was foul. The glands in the neck on that side were enlarged and tender; any lateral movement of the head produced pain. The skin of the neck was œdematous as also was that of the scalp, especially over the occipital region. The temperature was 104·6° F. and the pulse was uncountable (probably 160). The diagnosis arrived at was that it was probably a case of early gangrenous stomatitis. Surgical interference was mooted but was refused. Accordingly

---

[illegible] ol. i.

2 [illegible]

I ordered a lotion[3] for frequent application to the interior of the cheek, giving at the same time two grains of bromide of potassium every two hours for six hours, subsequently every four hours. On the next day the cheek was not so swollen or tense, but the eye was closed by the œdematous lids. The inside of the cheek had lost its dusky colour; the dusky grey spot had disappeared, its site being occupied by a small zone of hyperæmia. The breath was not so foul. The cheek could bear a moderate amount of manipulation; the glands in the neck were not so tender, and the œdema of the scalp was not so marked. A slight cough was present but there were no physical signs. The temperature was 103°. The child was taking a little milk. On May 2nd the temperature was normal, the cheek not so swollen, the œdema of the eyelids was disappearing, while [illegible] The child was taking his [illegible] ching convalescence. By [illegible] of the cheek was like a chronic superficial abscess pointing; there was a localised swelling of about the size of a hazel-nut, the skin over it being congested, but the swelling was solid in character. The child was taking its food well and sleeping well. The swelling gradually diminished in size, and by May 7th the cheek was normal. The child has subsequently remained in good health.

Recovery occurring without any loss of tissue negatives the view that it was a case of gangrenous stomatitis, and I have been unable to find any reference to cases of threatening gangrenous stomatitis undergoing spontaneous cure in the literature at my disposal. There was no evidence of its being a case of ulcerative stomatitis. When first seen it seemed very improbable that such a young child would make a perfect recovery from such an acute infection and in such a short space of time.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SUPPRESSION OF URINE SIMULATING CALCULUS ANURIA.

By Preston King, M.D. Cantab.,
HONORARY PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH

In recording this case I wish in the first place to thank Dr. J. Lindsay for his clinical notes and Dr. R. Waterhouse for his help at the post-mortem examination and in the preparation of the microscope slides.

The patient, a spare, healthy looking man, aged 58 years, was admitted into the Royal Mineral Water Hospital, Bath, on August 21st, 1908. He was suffering from "rheumatism" in the wrist and pain and stiffness in the right hip, the latter being the result of an accident 12 months before. The heart and lungs were normal, and the urine had a specific gravity of 1015 and was free from albumin. Nothing occurred to call special attention to his case until he had been in the hospital a month. Then on Sept. 22nd he had a sudden attack of epigastric pain, followed by vomiting. On the next morning he seemed much better and, except for a little tenderness on palpation of the left kidney, nothing abnormal could be found, but he said that he had passed no urine since the attack of pain on the previous afternoon. The bladder seemed empty and this condition was confirmed by the passing of a catheter. More careful inquiries were now made into his past history, but beyond remembering that about ten years ago he had for a few weeks an attack of frequent micturition at a time "when his nerves were out of order," he could tell us nothing to throw light upon his case. He had had no urinary troubles since and at no time had there been any symptoms pointing to stone. From this time onward, until his death on Sept. 29th, there was an absolute suppression of urine.

The tenderness over the left kidney seemed to point to the fact that there, from whatever cause, was the seat of the trouble. Was that kidney blocked by a calculus? And, if so, what was the other kidney doing? Were its functions suspended through reflex nervous agencies? Or was it non-existent? The usual treatment for suppression having been tried without success, I asked Mr. R. J. H. Scott to see the patient with me with a view to operation. This he kindly did, but after consultation it was decided not to operate, and the event proved that surgery would only have hastened the natural issue. There was a little muscular twitching the day before the patient died, and he was sick again, but except for this there had been an entire absence of symptoms, and I had found it very difficult to make his friends understand the serious condition he was in. There was no uræmic smell in his breath or skin, and his mind remained perfectly clear up to within five hours of his death.

At the post-mortem examination the bladder was empty and contracted. The right kidney was, for all practical purposes, absent, being represented by a small thin-walled irregular cyst containing some clear fluid, and its ureter was a solid cord. The left kidney was enlarged, weighing seven ounces, and there were many small cysts on its surface containing a turbid yellow fluid. On section it was engorged, the capsule stripped readily, and the pelvis was injected. There was no calculus or other form of obstruction either in the kidney or ureter, which was patent throughout. Microscopically in this kidney the epithelial cells of the convoluted tubes were small and misshapen, their protoplasm granular, and their nuclei indistinct; many tubules contained coagulated material; the glomeruli showed no noteworthy changes. There was much small-celled infiltration around the blood-vessels and an increase of connective tissue in the medulla.

This case is of interest as an instance of non-obstructive suppression occurring in a man with only one kidney, and not followed by the usual symptoms of uræmia. If a stone had been found the case would have been one of calculus anuria, and there would have been nothing especially remarkable about it. In calculus anuria a satisfactory explanation for the absence of uræmic symptoms has, I believe, not been given. Fagge suggested that this might be due to the still healthy kidney changing the chemical constitution of the waste products, and rendering them incapable of producing uræmia, notwithstanding that they are retained in the body. But, however this may be with a healthy kidney, it would hardly seem to explain the absence of symptoms in the present case where the only kidney was diseased.

Bath.

A CASE OF APPENDICITIS PRESENTING SOMEWHAT UNUSUAL FEATURES.

By David Ligat, F.R.C.S. Eng.

A man, aged 40 years, a farm labourer, felt "out of sorts" on July 10th. The next day he felt rather better, but had to give up work on the 12th, when I first saw him. I found him in bed. He was moderately jaundiced. He had not felt sick nor had he vomited. He was not constipated. The fæces were of normal colour. The urine contained bile pigment. The tongue was dry and furred. He denied ever having had previous abdominal pain. The pulse was 120 per minute and the temperature was 102° F. There were [illegible] immediate operation and found the parts in the following condition.

The appendix was about 3½ inches in length and ran vertically upwards on the outer aspect of the ascending colon. It was straight. Its distal third was gangrenous. Pouting from the antimesenteric border of the gangrenous portion was a foreign body. This afterwards proved to be a true enterolith of oval shape and of the size of a bean, quite hard, and giving a metallic ring when allowed to fall on a plate. The meso-appendix was also gangrenous and its vessels were thrombosed. About a teaspoonful of offensive chocolate-coloured pus escaped. There were no limiting adhesions. The appendix and its mesentery were removed and the cavity drained. The pulse and temperature did not fall after operation. There was no general peritonitis, the abdomen remaining flat and soft, and the bowels acting well to calomel on the third day. The appendix region drained well. The patient had no nausea nor was he sick. The jaundice became more intense for the four days following operation, but was decidedly less during the next two days. The tongue remained dry and furred. There was some tenderness over the hepatic area. There were no rigors but the patient was frequently drenched in sweat, the temperature then falling for a short time to 96°, the pulse remaining between 120 and 125. On the fifth day after operation the pulse was 135 and the temperature 103°. The patient died on the following day, six days after operation and the tenth day of the attack. Unfortunately a post-mortem examination was not obtainable, but there can be little doubt that death was due to infective pylephlebitis.

---

[3] R. Chlorate of potash, grs. x.; gly. acid bor., ʒ iss.; aq. ad ℥ i.; m. f. lotio.

The following points seem of interest:—1. That although the stone, of relatively considerable size, must have been situated in the appendix for years the patient had never had the sightest abdominal pain in the region of the appendix. 2. That although the pathological changes actually present were so profound, the patient at no period either before or after operation was nauseated, sick, or constipated. 3. The early non-obstructive jaundice. No doubt the portal venous circulation was already infected when I first saw the case on the third day of attack. 4. The fact made apparent at operation that the vessels of the meso-appendix were thrombosed and the mesentery itself gangrenous.

Hastings.

A CASE OF TRANSIENT ATAXY FOLLOWING DIPHTHERIA.

BY H. O. BUTLER, B.A., M.B., B.C. CANTAB.

THE patient was a healthy male, aged 26 years. He had complained of a painful throat the day before I saw him. I then found that his right tonsil and a large portion of the soft palate were covered with a thick greyish-black membrane. Within two hours I injected 8000 units of antitoxin, and in this short space of time I noticed that the membrane had nearly doubled its area. The next morning 2000 units more were injected. This caused rapid disappearance of the membrane at first, but after two days a fresh membrane appeared and spread with nearly the same rapidity as the first. 10,000 units were then injected, and on the following day, as I was doubtful if this was enough, 6000 units more. The membrane rapidly disappeared after this. Bacteriological examination had previously shown that organisms morphologically resembling diphtheria bacilli were present. From the fourth to the eighteenth days vomiting shortly after food and most marked constipation were present. A large variety of pills and enemata had next to no effect; and, rightly or wrongly, the case gave me the idea of a paralysis of a portion at any rate of the small bowel being present. After the eighteenth day, however, this gradually passed off. Five weeks after the onset of the illness he complained of difficulty in swallowing. This, however, was never marked and persisted for about a fortnight, being due to a soft palate paralysis. About this time—that is, about seven weeks after the onset—the patient began to complain of numbness and tingling sensations in the feet, and I found that his gait was typically ataxic. The knee-jerk was present at this time. He rapidly became worse and after seven days was quite unable to do anything by himself owing to the ataxy and loss of muscular sense. It was impossible for him to stand or walk. He could not feed himself, and if I offered to shake hands he would seize the back of his head or his nose. When it was dark and he was unable to see, he was absolutely and completely helpless. This state lasted for a month and then gradually cleared up in another three weeks, with the exception of the right arm which he complained he was unable to use properly. On investigation, however, this appeared to be due to stiffness in the shoulder-joint which lasted on and off for about five months. After the ataxy had persisted for two weeks the knee-jerks disappeared and remained absent for another two weeks and then gradually returned. At no time were there ever any eye changes or wasting of any muscles, and, with the exception of the before mentioned slight difficulty in swallowing and constipation, no motor paralysis. For a few days a slight retardation of painful stimuli on the outer sides of the legs was noticed, but no areas of anæsthesia were found. All this time the patient complained of numbness and tingling in the feet and hands.

Treatment consisted solely in giving a mixture containing strychnine, which was started at the onset of the illness and continued steadily. Whether the large amount of antitoxin given had anything to do with the condition it is not for me to say, but I have noticed an ataxic gait in children before now who have had not more than 6000 units.

The pathology of the condition, I should fancy, is simple: a peripheral neuritis of the afferent nerves accounts for all the symptoms. Dr. Charles R. Box in Vol. XXVIII. of St. Thomas's Hospital Reports gives an excellent account of a typical case, and he gives the following list of references to cases of ataxia following diphtheria, which may be of use:—

Sutton Court-road, W.

A CASE OF ACUTE PULMONARY ŒDEMA.

BY CHARLES E. DENNING, L.R.C.P. & S. IREL., L.M.

IN a paper in THE LANCET of Dec. 7th, 1907, p. 1606, Dr. Leonard Williams drew attention to the condition known as acute pulmonary œdema and elicited reports of several cases, including one by myself which appeared in THE LANCET of July 18th, 1908, p. 158. The following notes relate to another case of this important and interesting condition that has recently come under my care:—

On the afternoon of Feb. 24th I was called to see a man who had arrived that day in Epping. When I visited him, about 5.45 P.M., he was sitting in the dining-room, feeling quite comfortable, having had tea. He explained that he had been ill for a fortnight with pleurisy followed by effusion; that he had been in bed for some days and had then been allowed to get up and to go for short walks; that the day previously his temperature was something over 100° F.; and that he had come home contrary to the wishes of the medical man in attendance upon him. His age was 43 years. I found his temperature to be 100·2°, the pulse 100, and the respirations 24, and I recommended his going to bed in order that I might make a physical examination. I remarked upon a small quantity (about three teaspoonfuls) of what looked like pus which was in a dish beside him and was informed that he had expectorated this only a few minutes before and that he had not previously seen any like it. Whilst speaking to me he began to cough and in a few minutes this cough became incessant and distressing, and he commenced to expectorate mouthfuls of a frothy fluid which seemed to flow continuously into his mouth. From a state of comfort in less than five minutes his condition became most alarming. He had jumped to his feet and, leaning both hands on the table, was spitting out a stream of frothy fluid into a basin in front of him, and he appeared to be almost suffocating. I gave him some brandy and in 15 minutes from the commencement of the attack I injected 1-30th of a grain of strychnine. The coughing and expectoration continuing, in another 15 minutes I gave a second injection of strychnine (1-30th of a grain), atropine (1-100th of a grain), and also some champagne. In five minutes more the attack was over and the patient now lay back in a chair utterly exhausted, collapsed, and cyanosed. The respirations were 40 and the pulse was 120. I feared that he would die at any moment. However, with further stimulants and another injection of strychnine and atropine he rallied, although for some hours his condition was one of extreme exhaustion, the respirations remaining at 40 and the pulse at 120.

In the 35 minutes during which the attack lasted the man had expectorated about a pint of pink-coloured frothy serum, which later separated into a pink fluid beneath a thick layer of minute froth just like yeast. In about an hour the cough returned, although this time it was of quite a different character, and in a few minutes he had expectorated four ounces of pus, similar to that which I had previously remarked upon; and during the next 24 hours over a pint was discharged. This on examination showed the presence of a large number of pneumococci. His heart sounds were normal.

The sequence of events appeared to be, first, a rupture of an empyema into a bronchus just at the time of the expectoration of the small quantity of pus. This was followed by an attack of acute pulmonary œdema, and on recovery from the shock came the free discharge of the empyema. Convalescence was uninterrupted and of no special interest.

A most interesting point appears to me to be the fact that there was no cardiac mischief present.

Epping.

Reviews and Notices of Books.

A Text-book of General Pathology for the Use of Students and Practitioners. By J. MARTIN BEATTIE, M.A. N.Z., M.D. Edin., Professor of Pathology and Bacteriology, University of Sheffield; Honorary Pathologist, Sheffield Royal Infirmary and Royal Hospital; and W. E. CARNEGIE DICKSON, M.D., B.Sc. Edin., F.R.C.P. Edin., Lecturer on Pathological Bacteriology and Senior Assistant to the Professor of Pathology in the University of Edinburgh; Assistant Pathologist, Royal Infirmary, Edinburgh. With 162 illustrations and four coloured plates from original preparations. London: Rebman, Limited. 1908. Pp. 475. Price 17*s.* 6*d.* net.

THE general plan and scope of this new text-book of pathology are based upon the teaching of the Edinburgh School, and in their preface the authors acknowledge their indebtedness to Professor W. S. Greenfield. They give as the *apologia* for their book the fact that some of the fundamental views of that school, though based upon careful experimental investigations and upon extensive experience of human morbid anatomy and histology, have not, in their view, received sufficient attention. As an example of this they refer to infarction. It must be admitted that the description of the results of vascular occlusion given in many text-books is far from satisfactory, and especially is this the case in regard to the conditions which determine the development of anæmic infarction and its relation to the hæmorrhagic variety. The account here given, as the authors admit, is not new, but is based on experiments upon the kidney and spleen in animals. It affirms that infarcts, in these organs at any rate, are at first always red, and that in small infarcts pallor supervenes in a few hours. In regard to the cause of the congestion of infarcts, the theory of reflux from the veins proposed by Cohnheim is negatived, and the view of Litten and others that it is the result of collateral blood-supply is confirmed by experimental data. As a whole, the mechanism of infarction here described appears to us to be clear and intelligible and is not obscured by theoretical speculations.

The book is divided into seven chapters and is copiously and well illustrated, for the most part by reproductions of photographs and micro-photographs of actual specimens. The coloured plates are also well executed and illustrate the microscopical appearance of various degenerations and of the blood corpuscles and blood parasites. The first chapter is devoted to the cell in health and disease and gives a clearly written and up-to-date account of the fundamental facts in regard to cytology, with special details of the normal and abnormal forms of mitotic division. Under the heading of the composition of protoplasm an outline of the recommendations of the Chemical and Physiological Societies of Great Britain in regard to the nomenclature of the proteins is given. Various cytoplasmic and nuclear changes are also briefly described. This chapter forms a useful introduction and is worthy of special commendation.

The second chapter deals with general retrogressive processes and includes accounts of the various degenerations and infiltrations as well as of necrosis, gangrene, and atrophy. These are all described in some detail and the results of recent work are incorporated. Fatty, waxy, and calcareous changes are dealt with in more detail than is usual in a book of this size and we have nothing but praise for this section of the book. The third chapter on disturbances of the circulation contains good accounts of venous obstruction, dropsy, œdema, chronic venous congestion, and thrombosis. In reference to the process of clotting, no mention is made of thrombokinase or of the possible importance of hæmagglutination in relation to thrombosis. This chapter contains the description of infarction, to which we have already referred.

The description of inflammation and repair usually forms a very good criterion for estimating the value of a text-book on general pathology, and in this connexion we may at once assert that the manner of considering these subjects in the fourth chapter is thoroughly to be commended. The description is clear and concise, and the various factors involved are differentiated and considered in an admirably lucid style. The fifth chapter extends to over one-quarter of the book and is devoted to progressive tissue changes, including under this heading hyperplasia, hypertrophy, tumours, and the granulomata. The consideration of the problem of tumour formation is critical and well arranged; the various theories are briefly enunciated and discussed. The classification adopted is that of Professor Adami into hylomata and lepidomata or "pulp" and "rind" tumours respectively, with their subdivisions. This classification, though ingenious and scientific, has hardly yet achieved sufficient recognition to warrant its use in a text-book intended for students and practitioners; moreover, it introduces a new nomenclature of somewhat cumbrous character. The sixth chapter deals with animal parasites, classified according to zoological principles. The descriptions are adequate and the illustrations are clear and abundant. The last chapter contains within comparatively small compass a useful *résumé* of the general principles of immunity and of the theories advanced to explain it.

The text-book is one which should prove of great value to students and practitioners, for it is concise without being obscure, and gives reliable descriptions of the main data of general pathology. It would be well in a future edition to include more discussion of the phenomena and mechanism of fever.

The Criminal Responsibility of Lunatics. By HEINRICH OPPENHEIMER, M.D., LL.D., &c. London: Sweet and Maxwell, Limited. 1909. Pp. 275. Price 10*s.* 6*d.*

THE problem of the criminal liability of persons of unsound mind has passed through several phases. For centuries none but the grossest forms of insanity were recognised as excusing the patient from the legal consequences of some delinquency. As the barbarism of the Middle Ages has in part passed away so has the position of the criminal lunatic ameliorated, until unhappily, under the influence of certain schools of psychology, some have come to regard the criminal as insane because he is criminal. The scandal, happily comparatively rare in this country, which results when experts on identically the same subject are found to assume diametrically opposite positions is a grave one and calls for much reflection on the part of the medical profession. Dr. Oppenheimer usefully reminds us that the witness who proclaims as scientific facts certain ephemeral hypotheses, however ingenious they may be, merely brings into discredit the profession which he is for the moment representing. The medical man may remember that much of the treatment which is practised in up-to-date asylums is at least founded upon the hypothesis that the lunatic in most cases is capable of regulating his conduct, that is, that he knows his own likes and dislikes, is aware of the rules and regulations of the institution in which he is lodged, and where those rules clash with his personal predilections he is capable of shaping his conduct to accord with the rules rather than with his wishes. Dr. Oppenheimer argues that it is too transparent a sophism to require serious confutation if it is claimed that the insane mind is capable of being checked by the fear of such disciplinary sanctions but not by the threat of those of the criminal law.

To decide the question of the responsibility of an insane person, so far as hospital practice is concerned, may be easy. He is responsible or he is not, and perhaps not a single medical superintendent would, in these circumstances, hesitate to act. There are equally patients of whose responsibility even in the simple affairs of an asylum no medical superintendent would care to express any opinion at all. But place this same medical expert in the witness-box and we shall find in too many cases that the vaguest suspicion of insanity is put forward as a sufficient reason for the exemption of the accused from all the legal consequences of his acts. A witness may give it as his opinion that a person is insane, but it does not follow that that person is irresponsible for all he does, and we fear that the tendency now is, from a purely humanitarian point of view (which sometimes is mawkish as well), to suppose him irresponsible if unpleasant consequences are likely to ensue when the opposite view is taken. If, as the author puts it, it is conceded that very many acts of the insane are not insane acts at all, but spring from the same sources as those of rational beings, if it is an undisputed fact that the majority of lunatics understand the nature and quality of many of their deeds and are quite competent to distinguish right from wrong, if it is finally conceded that very frequently lunatics are quite capable of controlling their conduct, and are, moreover, influenced by fear of punishment, the case for holding them responsible, is, *pro tanto*, made out. Where all these conditions occur the lunatic's mind is amenable to the sanctions of the law. On the other hand, every criminal who can show that he has done some strange act in the past can nowadays hope, if his counsel seeks long and far enough, to find a medical man prepared to testify to his madness, of the nature, perhaps, of that wonderful clinical phenomenon, the "brain storm." In these circumstances it is, perhaps, unsafe to give *carte blanche* to the medical profession by making insanity the sole test of irresponsibility. Indeed, if a sufficiently high standard of mental health be erected, persons entirely free from mental defect would form the exception rather than the rule, and the propaganda directed towards the establishment of such a principle becomes neither reformatory nor progressive, but destructive of the fundaments of criminal justice. The tests which should in fact, so far as is possible, be applied are, firstly, whether the accused was aware of the nature and quality of the act, and secondly, if he could have refrained from it had he chosen to do so. The essential problem in truth lies in the application and findings of this second test.

In regard to moral insanity it is plain that the influences which restrain the ordinary individual from doing wrong are religious, moral, and legal. Where disease has destroyed two out of these three checks it is scarcely reasonable to remove the last barrier that stands between the criminal and the safety of society. Persons who are morally defective pass through life without conscience to restrain them and unless curbed by the hand of the law are left to the control of their appetites and passions alone, and we may then well hesitate to exempt them from criminal responsibility. Between full responsibility and complete irresponsibility there exists scale of diminished responsibility. As there are degrees o insane obliviousness to right and wrong, degrees of self control and degrees of insane impulse, the law ought t recognise the fact that the amount of guilt decreases in th same ratio as mental disease gains in intensity. Th difficulty, however, lies in the method by which we are t penetrate the human soul and determine the precise degre of responsibility.

The book shows a large amount of erudition. The autho has studied the laws of many countries, and has abstracted from them the articles bearing upon the subject of his work In his comments and conclusions he manifests a thoroughly judicial attitude, and for the sake of his medical readers he has presented a complex subject in terms of common-sense couched in good plain English. His conclusions are likely enough to arouse considerable opposition, but that must be the condition of a controversy in which the premisses of the argument are still the subject of inquiry, if, indeed, they are capable of being known at all.

Health and Common Sense. By WOODS HUTCHINSON, M.A., M.D., Lecturer on Clinical Medicine at the New York Polyclinic; late Professor of Comparative Pathology and Embryology, University of Buffalo; Lecturer on Comparative Medicine in the Medical Graduates' College, London. London, New York, Toronto, and Melbourne: Cassell and Co. 1909. Pp. 334. Price 6*s.* net.

THIS book consists of a series of chapters dealing in popular language with matters relating to personal and domestic hygiene. It is in a sense a presentation of elementary physiological facts in a simple form with their application to the ordinary conduct of life. Dr. Woods Hutchinson writes clearly and forcibly; and his observations are practical. His style is crisp and allusive, and his illustrations or similes are to the point, and are not infrequently amusing. He is uncompromising in his exposure of common fallacies, and is particularly scathing in his denunciation of many of the popular superstitions as crystallised in aphorisms, proverbs, and saws, which he irreverently describes as "gems of senility," and again as "little more than the attempts of mediocrity and cowardice to console themselves for their lack of success." A proverb of almost any kind seems to excite him to turn and rend it, and some of the most cherished maxims of our copybook days come in for very severe handling. It is only fair to say that he gives reasons for his opposition, and that he makes a very good case for his views.

After a chapter on the ancestry of health indicating the broad outlines of the evolution of man's organisation, he exposes some diet delusions. He dismisses Professor Chittenden's work on the protein minimum diet very scornfully; he pillories what he calls the fish-phosphorus-brain theory, the prejudice against pork as an article of diet, vegetarianism, "breakfast foods," and the superiority of brown over white bread. He discusses in an interesting manner certain foods, which he classes together under the heading of "poison foods," characterised often by considerable nutritive value, but liable, especially in susceptible persons, to produce gastric irritation and even toxic symptoms, such as certain fruits, shellfish, nuts, and cheese.

The author's views on sleep, about which he writes at some length, are well expressed in the lines which he quotes:—

> "Blest be the man who first invented sleep,
> But curst be he with curses loud and deep
> Who first invented and went round advising
> That artificial cut-off, early rising"

The advice in regard to sleep is in brief to take as much as possible. Sunshine and fresh air he characterises as the real angels in the house, and his plea for ventilation and for care in the choice of sites for house building is forcible and good. He gives advice in regard to bathing, care of the complexion and clothing, and has a chapter on the sins of the shoemaker.

Four chapters are devoted to certain special aspects of child life and education. They are eminently readable and contain many sound and original suggestions. Dr. Woods Hutchinson is a firm believer in the educational value of play for the child, both mentally and physically, and he draws an interesting picture of the ideal school. His last chapter is on the health of the middle-aged man, and is characterised by the same breezy optimism as the rest of the book. For him instinct and the general experience of mankind are safer guides than the doctrinaire rules of pseudo-scientific faddists. Sometimes, perhaps, in his enthusiasm for instinct he makes statements which are open to question—e.g., that the danger of over-eating has been enormously exaggerated; but his book should command a wide circle of readers, for he is always interesting and never abstruse and technical. It appears from a note at the beginning of the book that it was originally called "Instinct and Health," but apparently at the suggestion of the publishers this was altered to "Health and Common Sense," and perhaps the best notice we can give to the book is to express the opinion that no better title could be found.

Les Maladies du Cœur et Leur Traitement. (Diseases of the Heart and Their Treatment.) Par H. HUCHARD, Médecin de l'Hôpital Necker, Membre de l'Académie de Médecine. Paris: Librairie J. B. Baillière et Fils. 1908. Pp. 228. Price Fr. 6.

THIS book consists of nine lectures on diseases of the heart and their treatment. The subject is dealt with from a purely clinical and practical standpoint, and the dogmatic and didactic style, adorned by the literary grace of their distinguished author, renders these lectures particularly interesting and instructive. Their object is avowedly practical, and Dr. Huchard gives the results of his own ripe experience of treatment in the various forms of cardiac disease. He wishes to disprove the nihilistic views of some of the earlier French authorities, such as Brouissais, who said that from the medical standpoint they are "maladies of pure curiosity," and Sénac, who said that "their study gives the useless satisfaction of knowing better the impossibility of curing them."

In his first lecture Dr. Huchard emphasises the importance of the study of the disturbances of function, such as dyspnœa, insomnia, tachycardia, palpitation, syncope, arrhythmia, and præcordial pain, from the point of view of diagnosis and treatment. In regard to dyspnœa he differentiates a mechanical and a toxic form, the former due to simple cardiac failure with defective aeration, the latter occurring in cases of arterial degeneration and associated with defective renal activities. The prognosis and treatment in these two forms are markedly different and are carefully worked out.

In the second lecture the group of "arterial cardiopathies" is differentiated—that is, defects in the heart's action the result of arterial degenerations. Dr. Huchard describes an arterio-sclerotic form of mitral stenosis which he regards as not uncommon. He admits, however, that the physical signs are usually slight, but maintains that the symptoms are very abundant and suggestive. In regard to all these arterio-sclerotic forms of disease he urges the importance of treatment by milk regimen and diuretics, with a view to diminish the intoxication, which is the essential factor in their production as well as in the genesis of their symptoms.

The third lecture is devoted to functional diseases of the heart, and in the fourth a number of errors both of diagnosis and of treatment are detailed. This lecture is of special interest as it contains many personal observations of value, and it exposes many fallacies in regard to the treatment of heart diseases. The fifth lecture deals with the treatment of arterial cardiopathies. Four stages, each with a different line of treatment, are described: the first or arterial stage, treated by careful diet and physical measures; the second or cardio-arterial, treated by means of a milk and vegetarian diet, by nitrites, diuretics, and tonic doses of digitalis; the third or mitro-arterial stage, characterised by dilatation of the cavities and of the valvular orifices, treated by a milk diet, by theobromine, and by digitalis in larger doses; and the fourth or cardiectasic stage, treated by bleeding, by salt-free diet, and limitation of ingested fluids. The sixth lecture deals with the treatment of heart disease resulting from chronic endocarditis. In the seventh lecture Dr. Huchard develops his dictum that "the arterial cardiopathies commence by intoxication, continue by intoxication, and finish by intoxication." In the eighth and ninth lectures the mode of action of certain curative and hygienic measures is discussed.

Dr. Huchard's lectures are both suggestive and helpful, and they should be widely read, for they insist upon the importance of a careful study of symptoms as well as of physical signs in regard to the treatment of individual patients. We have already spoken of the book as dogmatic, but this has its merits.

A Compendium of Food Microscopy. By EDWYN GODWIN CLAYTON, F.C.S., F.I.C. London: Baillière, Tindall, and Cox. 1909. Pp. 431. Price 10*s.* 6*d.* net.

THE value of the microscope in the examination of foods and drugs was proved in a striking way in the researches of the late Dr. Arthur Hill Hassall, who applied the instrument with considerable success to the detection of adulterants in the work of inquiry undertaken by him for this journal in the early "fifties." In committing the results to publication it should be remembered that Dr. Hassall had the advantage of the services of a skilled artist, Mr. Miller, who made the drawings which were reproduced in the reports of the now famous LANCET Analytical Sanitary Commission. Many of these were reproduced in Dr. Hassall's book on "Food: its Adulterations and the Methods for their Detection." Later Mr. Clayton, the author of the volume before us, joined Dr. Hassall in analytical practice, and therefore none could be better qualified than himself to write a revision of the microscopical portions of Dr. Hassall's work. It will soon appear to the reader that Mr. Clayton has done something more than mere revision; he has extended the application of the microscope to the examination of foods and drugs which were unknown in Dr. Hassall's time and he has therefore placed in the hands of all those concerned to maintain the purity of foods and drugs a guide which will afford them very material help in their work of fighting modern methods of sophistication. He has divided the book into four sections, the first dealing with foods derived from vegetable sources, the second with foods derived from animal sources, the third with tobacco, drugs, bitters, and colouring matters, and the fourth with water. The last has obviously involved an amount of fresh matter in view of the advances made in the application of the microscope by modern inquirers to the examination of water intended for drinking purposes. The drawings are well done and will afford a valuable source of reference to the microscopist busily engaged on questions connected with the detection of adulteration. This is a good book, for it not only pays tribute to a man who undoubtedly did pioneering work of the most valuable kind in connexion with microscopical methods for revealing adulteration, but it encourages the further application of the microscope to similar ends.

JOURNALS AND MAGAZINES.

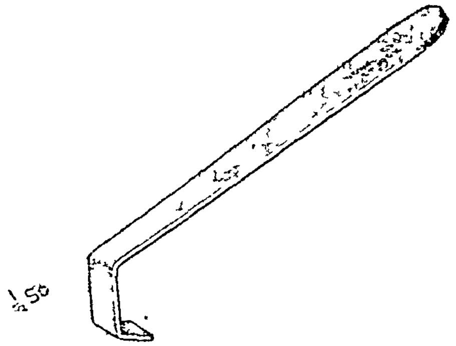
Proceedings of the Royal Society of Medicine. Vol. XI. No. 8. June, 1909. London: Longmans, Green, and Co.—This number of the Proceedings of the Royal Society of Medicine is largely occupied by reports of cases presented to the several sections, many of which we have published. The chief contribution to the Section for the Study of Disease in Children is Dr. F. Parkes Weber's careful account of a case of Congenital Obliteration of the Bile-ducts with Hepatic Cirrhosis, in which a streptococcal infection was the final cause of death. The Dermatological Section is devoted to a full report of Dr. Louis Wickham's demonstration of his methods and results in the Therapeutic Applications of Radium. In the Epidemiological Section Dr. John Brownlee presents certain considerations on the Causation and Course of Epidemics, in which he examines the curves of incidence in several epidemics in relation to known mathematical laws, an interesting and complex piece of work which is capable of extension. Mr. M. Greenwood follows with a statistical examination of the Problem of Marital Infection in Tuberculosis, which leads to the conclusion that our statistical data are at present far from sufficient to settle the question. The keen discussion on these papers, which is well reported, echoes the debate on Heredity in Relation to Disease which occupied so much of the attention of the Royal Society of Medicine earlier in its late session. The Laryngological Section is entirely devoted to clinical records and the Medical Section to papers on the Serum Treatment of Typhoid Fever, by Dr. R Tanner Hewlett, Dr. E. W. Goodall, and Mr. R. M. Bruce. These authors contribute a note on an Ophthalmo-Reaction obtained with a Solid Typhoid Endotoxin, which does not seem to be diagnostic of enteric fever. The Obstetrical Section reports a discussion upon the Management of Rupture of the Uterus, following upon papers by Dr. T. W. Eden and Dr. A. Lionel Smith concerning that grave accident. In the Odontological Section Mr. W. Warwick James writes on the Eruption of the Teeth. The Otological Section records only notes of cases. In the Surgical Section Mr. J. Hutchinson's paper on Auto-inoculation and Re-infection in Syphilis, which has appeared in our columns, precedes an account of Jejunal and Gastrojejunal Ulcer following Gastrojejunostomy, by Mr. H. J. Paterson, who has collected a very careful bibliography of the condition in question. The Therapeutical and Pharmacological Section contains the instructive paper on the Results of a Year's Use of Vaccines in General Medicine, which Dr. W. Hale White and Dr. J. W. Eyre recently published in THE LANCET; and also Dr. William Bain's paper on the Interaction of Digestive Ferments. We note that the next number of these Proceedings will be issued in October, and will include the title-pages and index for the second volume.

New Inventions.

A NEW RETRACTOR AND ARTERY FORCEPS.

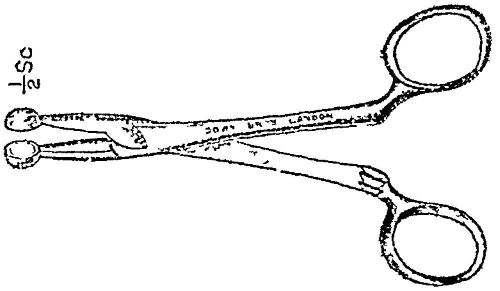
I SHOULD like to bring two instruments which I have devised to the notice of other surgeons. The first is a retractor for the splitting operation for appendicitis. As I consider the splitting operation in appendicitis the only justifiable one, I have thought that the modification in the form of the retractor shown in Fig. 1 obviates one or two objections common to those in ordinary use, because (1) the part introduced in the wound is always in the same plane as the muscle retracted, consequently it is not lacerated; (2) the width of the retractor is just enough to give a good field of operation without unduly stretching the external oblique; and (3) the handle is placed at an angle to accommodate the assistant's fingers below, whilst the thumb lies on the upper surface.

FIG. 1.



The other instrument (Fig. 2) is an artery forceps of a new pattern. The difficulty of tying beyond the points of the artery forceps in deep situations led me to try a globular end to the Spencer Wells, and I can now, after a fair trial, attest to the great advantages thereby attained, because (1) they do not take up more tissue than other forceps; (2) the surgeon can tie off the artery by himself and take off the forceps afterwards; (3) once the ligature is beyond the greatest circumference of the globular end it must tie off properly if it is tied tight enough, and the certainty of this saves much time in operating; (4) they will pick up the smallest and most fragile artery; and (5) the circular grooves on the inner surface give a very firm hold.

FIG. 2.



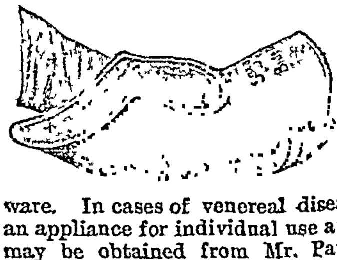
Messrs. Down Bros. have taken great pains in carrying out my ideas in both these instruments which they have made excellently.

A. Z. C. CRESSY, M.R.C.S Eng.

Wallington.

THE SEXA-BIDET.

THE Sexa-Bidet is a very convenient appliance either for simply washing the parts in question or for the application of medicated lotions. When in use it is held in the hand in a horizontal position as shown in the illustration, the curved edges being pressed firmly against the body; it may also be partly filled with water when standing upright on a table, like an ordinary jug. It is quite portable, measuring 13 inches in its greatest length and about 5 inches in width. The material is highly glazed white earthenware. In cases of venereal disease the advantages of such an appliance for individual use are obvious. The Sexa-Bidet may be obtained from Mr. Paul Metz, 29, Newhall-hill, Birmingham. There is a slight difference in the curvature of the open end in the patterns used by males and females respectively; the prices are 4*s.* 6*d.* for the former and 5*s.* for the latter.



THE
BRITISH MEDICAL ASSOCIATION.

SEVENTY-SEVENTH ANNUAL MEETING
AT BELFAST.

THE SECTIONS.

MEDICINE.

FRIDAY, JULY 30TH.

President: Professor JAMES ALEXANDER LINDSAY (Belfast)

Dr. H. S. SOUTTAR (Brentwood) described the experiments which he and Dr. Theodore Thompson had made in order to secure

A Practical Form of Gastroscope.

At first they considered it axiomatic that a gastroscope must consist [illegible] during [illegible] the seg[illegible] proved to be wrong, although one form was constructed on this principle. Experiments on the cadaver proved futile except for purposes of measurement. In order to determine the normal form of the œsophagus and to what extent it could be straightened they passed metal-lined bougies and examined their shadow on a fluorescent screen by means of the X rays, the patient bending his back and moving his head in various directions. By experiments upon themselves [illegible] rate a straight [illegible] fauces to the [illegible] cardia such a straight rod could not be carried, since it would impinge on the lower dorsal vertebræ. The lower end of their instrument was therefore bent forwards at an angle of 30°. At the upper end of the tube an oral portion was added at an angle of 60° with the œsophageal limb. In this way there was evolved an instrument with only two angles, which conformed exactly to the anatomical requirements and proved easy to pass, for the forward tilt of the beak, instead of being a danger, proved to facilitate its passage. When it was being passed the patient's head and neck were brought well forward, accentuating the dorsal concavity, into which the angular instrument fitted snugly; during the descent of the instrument the head and neck were allowed to fall back. Dr. Souttar and Dr. Thompson had never found any difficulty in passing the instrument and had observed no ill effects from its use. The preparation of the instrument proved to be very expensive, since six complete instruments were made by Dr. Souttar himself before a practicable form was reached, and the authors acknowledged their indebtedness to the London Hospital Medical research fund for assistance. The instrument consisted of three layers—an outer protective layer of steel, a middle supporting layer of metal covered with silk, and an inner tube which was capable of rotation, this rotation being transmitted to the nose-piece of the instrument. An arrangement of mirrors and a lens of very short focal length enabled a small image to be formed near the eye end of the tube, and this image was examined by an eye-piece. Owing to the possibilities of moving the tube and of rotating the nose-piece practically the whole of the inner surface of the stomach could be examined, but it was necessary to inflate the stomach with air for this purpose. In using the gastroscope the stomach should, if possible, be empty, and it was shortly beforehand washed out by means of a tube. It was preferable that the patient should be under an anæsthetic. The mouth was opened by means of a Mason's gag and the head lifted forwards. A full-sized bougie was first passed as a precaution, and after its withdrawal the nose of the gastroscope was guided into the pharynx by the finger. At the cricoid cartilage some resistance was always met from tilting of the cartilage and from spasm of the upper end of the œsophagus. Gentle manipulation soon enabled the instrument to pass, and it glided down the œsophagus by its own weight. Slight spasm was again met with at the cardiac orifice. As the instrument glided down the head was gradually allowed to fall back again. The pump was attached and the stomach inflated, whilst an assistant percussed out its lower border. The light was switched on and the nose rotated and deflected until the whole mucous membrane had been systematically examined. Dr. Souttar claimed that no more manipulative skill was required than in the use of a cystoscope.

Dr. THEODORE THOMPSON (London) gave an account of the results achieved by this instrument. He pointed out the great importance of early diagnosis in the graver disorders of the stomach, notably in carcinoma and ulcer. It was desirable that carcinoma of the stomach should be diagnosed before the tumour became palpable, by which time the lymphatic glands had almost invariably become infected. It was [illegible] at pres[illegible] the pre[illegible] was the [illegible] of the stomach in all cases of persistent gastritis in adults. In an apparently healthy stomach the first appearance observed was of a bright red reflex. On carefully focussing with the eyepiece the folds of mucous membrane could be seen running transversely across the field, and there were numerous bright specks of light due to the reflexion of light [illegible] us on the surface. At the pyloric end [illegible] of acute gastritis, of a case of anæmic mucous membrane of a stomach with petechiæ, of another with gastric ulcer, and of another with pyloric carcinoma

Dr. LEWIS A. SMITH (London) and *Dr. D. W. SAMWAYS* (Mentone) both spoke briefly and Dr. SOUTTAR replied. A demonstration of the instrument was given.

Dr. A. GORDON GULLAN (Liverpool) read a paper on a

Unique Case of Hour-glass Contraction of the Stomach,

making special reference to diagnosis. The patient was a woman, aged 36 years, who had been subject to attacks of vomiting since her school days, these attacks being independent of pain and also of the ingestion of food. Later in life gastralgia had occurred and two years before severe hæmatemesis and more frequent vomiting with signs of dilatation of the stomach appeared. These symptoms at first disappeared under treatment by lavage in the Liverpool Stanley Hospital, but soon recurred after her return home, and then marked peristalsis of the stomach manifested itself. As all forms of medical treatment were unavailing a gastro-jejunostomy was performed, but the patient died. The stomach was found to be enormously dilated, extending [illegible]s; it was somewhat twisted [illegible] to two large portions, both [illegible] stomach. The proximal portion was the larger one and overlapped the distal, to which it was fixed by adhesions, and thereby preventing the fissure between the two portions from being recognised during life, and the two parts from separating from each other. The pylorus was tough and fibrous and only transmitted a small quill, and this fibrous tissue was continued along the lesser curvature for about four inches to the spot at which the hour-glass constriction occurred; this was so narrow that the little finger alone could pass through the opening. Dr. Gullan discussed the various tests useful in the diagnosis of hour-glass contraction of the stomach, and showed that many of them were absent in this case owing to the adhesions, the twisting, and the overlapping of one part of the stomach over the other. For these reasons the bilobed appearance could never be detected during life.

Dr. PURVES STEWART (London) read a paper on the

Technique and Results of Schlosser's Method of Treatment of Tic Douloureux.

He described tic douloureux as the most severe of all forms of physical pain, and stated that owing to its inveterate character and its tendency to increase in frequency and severity the patients were ultimately driven to chronic morphinism or to suicide. It had been a therapeutic despair for many years, since operations on the peripheral branches of the nerve only gave temporary relief and produced deformity, while the operation for excision of the Gasserian ganglion was one of considerable mortality and led to grave deformity from muscular wasting, with anæsthesia of the skin, nose, eye, and mouth, and occasionally a destructive ophthalmia in the anæsthetic eye. He then referred to the results obtained by Professor Schlösser from the injection of alcohol into the foramina of exit of the branches of the nerve from the skull. These injections might produce temporary cutaneous anæsthesia, but they led to a cessation of the pain, often for prolonged periods. Among 120 cases there was an average period of relief lasting from 10 to 11 months, and this without scarring, deformity, or permanent anæsthesia. The apparatus necessary was a stout hollow needle 10 centimetres long and 1½ millimetres in diameter, provided with a blunt stilette projecting beyond its point. The needle was marked in centimetres up to 5. The method was to push in the needle through the skin and then to project the blunt stilette through so as to avoid injury to vessels in carrying the needle to the foramen selected. The stilette was withdrawn and 2 cubic centimetres of alcohol of 75 per cent. strength, containing 2 grains of eucaine to the ounce, were injected. On withdrawal the puncture made by the needle was covered with collodion. No general anæsthetic was necessary, except in the case of the first division, the patient only feeling a transient flash of pain when the nerve was reached. The directions for reaching the foramina were as follows: (1) for the foramen rotundum, to enter at the lower border of the zygoma near its anterior end and to push inwards into the pterygo-maxillary fossa, the foramen being at a depth of 5 centimetres from the surface; and (2) for the foramen ovale to enter at the lower border of the zygoma 2·5 centimetres in front of its descending root, the foramen being at a distance of 4 centimetres from the surface. For the first division the needle should be introduced along the outer wall of the orbit for a distance of 3·5 centimetres. Sometimes one injection was enough to relieve the pain, but it was better to repeat it after two days and again after three or four days. The only complications observed were temporary stiffness of the lower jaw in the case of the second and third divisions, with some œdema of the lower lid and slight weakness of the facial muscles. With the first division there was marked œdema and sometimes transient paralysis of the external ocular muscles. Dr. Stewart quoted 15 cases which he had treated by this method, and in 12 of these, or 80 per cent., there had been recovery lasting from ten months downwards. He also described the three cases of comparative failure, and in conclusion said that although not a panacea the injections were a useful form of treatment.

Dr. W. B. MCQUITTY (Belfast) showed a case of this disease, and Dr. STEWART gave injections into the foramen ovale and foramen rotundum.

The paper was discussed by Dr. W. P. KENNEDY (Bath), Mr. H. A. BALLANCE (Norwich), Dr. TOM A. WILLIAMS (Washington), and Dr. O'SULLIVAN.

Dr. TOM A. WILLIAMS (Washington, D.C.) read a paper on

Tabes Dorsalis, its Rational Treatment in the Light of its Real Pathogenesis.

He deprecated the pessimism as regards treatment in this disease engendered by the dystrophic theory of its pathogenesis, and showed microscopical sections and lantern slides in support of the radicular theory which was first brought forward convincingly by Nageotte. Dr. Williams believed that there was a round-celled infiltration of radicular meninges and that this process differed only in intensity, but not in nature, from that upon the meninges elsewhere in syphilis, and showed that in some spots there might even be found a well-marked granuloma of minute size. This inflammatory process invaded the peri- epi- and endo-neural sheaths and impinged upon and injured the nerve fibrils. Their degeneration at this spot led to the degeneration of the posterior columns of the cord. The objection that these radicular changes were more often absent than present was only true as regards the macroscopic appearances. Careful search with the microscope always revealed meningeal exudates. The escape of the anterior roots was merely relative, and the rapid regeneration which occurred in them and which was possible because of their connexion with their trophic cells entirely negatived a dystrophic explanation. In the light of these observations Dr. Williams strongly recommended intramuscular or intravenous injections of mercury, and claimed that the local radiculitis which he regarded as the basis of the disease could be arrested in a large proportion of the cases. Intramuscular injections sufficed for most cases, except those threatened with rapid loss, of vision. The forms of mercury he employed were the cyanide or perchloride. For intravenous injection a very small and very fine needle of platinum-iridium was used, and after insertion it was recommended to draw out a drop of blood into the syringe in order to make certain that the vein had been entered.

Dr. THEODORE THOMPSON (London) said that in his opinion the radicular theory was not proved. He believed that in tabes dorsalis the symptoms were those of a lesion of the secondary sensory neurons, and that the lesion was situated at the junction of the primary and secondary neurons—namely, in the pericellular network in the posterior cornua—where the earliest changes were found. Tabes dorsalis was therefore a dystrophy beginning in the axonal terminations within the spinal cord, while the changes in the posterior roots were secondary.

Dr. GORDON GULLAN (Liverpool) endorsed Dr. Williams's view that early cases should be treated with antisyphilitic remedies and mentioned cases treated with benefit on these lines.

Dr. WILLIAMS briefly replied.

Dr. H. D. ROLLESTON (London) read a paper on

Pruritus in Lymphadenoma.

He stated that itching of the skin in lymphadenoma was not often recorded. In an analysis of over 90 cases it was only mentioned in three. In 20 cases at St. George's Hospital, London, he had found it in three. The causation of this symptom was unknown. It was not due to drugs. It had occurred before arsenic was given, and in one case it occurred after potassium iodide had been administered. There was no evidence that it was due to any special infiltration of internal organs. In a case under the care of Dr. W. Howship Dickinson the liver was found to be lardaceous, but it had occurred in cases without involvement of the liver. It was natural to suppose that it was toxic, and the occurrence of lardaceous changes in the liver in two cases supported this view, as did also its association with general exfoliative dermatitis. By analogy with the itching in jaundice it might be expected to be absent in children, and the earliest recorded case was at the age of 16 or 17 years. It might be one of the earliest symptoms, appearing even before enlargement of the glands. It might lead to infection of the skin, producing lesions simulating Hebra's prurigo. Dr. Rolleston had the impression that cases with early itching ran a rapid course. In regard to treatment, ordinary methods such as calcium chloride, carbolic acid, and antipyrin should be tried, but the itching was often so severe that morphia was necessary.

SURGERY.

FRIDAY, JULY 30TH.

President, Professor T. SINCLAIR (Belfast).

Mr. G. A. SYME (Melbourne) read a paper on

Some Unusual Cases of Echinococcus (Hydatid) Cyst, with Remarks on Diagnosis and Treatment.

He commenced by saying that he much preferred to call these cysts "echinococcus cysts," as was customary in Australia. The diagnosis of an unruptured echinococcus cyst in the liver or lung was fairly easy, especially since the introduction of X rays, for the cyst had a typical appearance in a skiagram. When the cyst was ruptured in the liver the diagnosis was not so simple, for the passage of the daughter cysts down the biliary passages might give rise to symptoms resembling biliary colic. When a cyst of the liver caused gradual absorption of the diaphragm and then burst into the lung it was liable to be mistaken for a primary cyst of the lung; but here also X rays might enable the diagnosis to be made. External violence might cause rupture and give rise to abdominal symptoms. The manner of reproduction of a hydatid cyst varied with the tension; in bone where there was little possibility of expansion the cyst reproduced itself exogenously, but when the cyst was able to grow freely and to become spherical, very few daughter cysts were formed. Mr. Syme decribed the case of a female patient, 24 years old, who had pain in the left buttock shooting down to the left ankle. The condition had lasted six months, with a swelling that was said to vary in size. She had lost flesh. On examination there was found a tense and elastic swelling in the left iliac region, and in Scarpa's triangle on the same side. The blood contained 9 per cent. of eosinophils. A skiagram showed much "rarefaction" of the ilium and sacrum. At the operation a cyst was found connected by a pedicle with a cavity in the sacrum. The patient had improved since. In another case a patient complained of pain on the right side of the chest, and on the right side of the spine there was a swelling. It was found at the operation that a cyst was involving a costovertebral joint and extended into the cavity of the chest, and cysts had also formed within the bodies of some vertebræ. Recovery followed. The value of the precipitin reaction in diagnosis was by no means certain, but eosinophilia was a useful help. In the treatment of echinococcus cysts it was possible sometimes to close the wound completely without drainage.

Mr. J. WARD COUSINS (Portsmouth) referred to two cases which he had seen of unsuspected subdiaphragmatic cysts accompanied with high fever. He also mentioned a case of enormous hydatid cyst of the abdomen which had been mistaken for ascites.

Mr. SYME, in reply, referred to a very large cyst arising from the liver in which huge masses of bilirubin were found.

Mr. P. J. FREYER (London) read a paper on

A Recent Series of 200 Cases of Enucleation of the Enlarged Prostate, with Special Reference to the Operation (1) in Octogenarians and (2) in Cases of Extremely Large Prostate.

He said that it was now eight years since the introduction of his method of enucleating prostates and he had described several series of cases; he had performed 212 prostatectomies since he read his last paper on the subject. Among these there were 17 cases in which the patient was over 80 years of age, one of them having a fatal result. Of the 644 cases on which he had operated there were 48 octogenarians, or if nine cases of the age of 79 years were included, there were 57 cases of patients 79 years of age and over, and of these six died. In his opinion there was just as much chance of success in the operation in an octogenarian as in a younger patient provided the kidneys were sound. Careful nursing was of the greatest importance. The size of the prostates which he had removed varied greatly, but the size of the incision need not be very large even for a very large prostate, for the prostate was elastic and could pass through an opening smaller than itself. The weight had varied from half an ounce to nearly 17 ounces, with an average of 2½ ounces; there were in all 644 cases, and the ages varied from 48 years to 89 years; there were 39 deaths, equal to a mortality of 6 per cent., but in the last 200 cases the mortality had fallen to 4·24 per cent. In 114 of the cases a calculus was removed at the same time.

Mr. A. B. MITCHELL (Belfast) congratulated Mr. Freyer on his success, and he expressed the opinion that the present operation was entirely due to Mr. Freyer.

Mr. WARD COUSINS asked if in severe septic cases the bladder was drained before the operation.

The PRESIDENT asked if the removal of a large prostate left an hour-glass-shaped cavity.

Mr. FREYER, in reply, said that the cavity previously occupied by the prostate became a part of the bladder cavity and disappeared as a separate space, though in some of the earlier cases a separate space did persist, and this was due to not passing the catheter sufficiently frequently when washing out the bladder. In cases where the tongue was dry and the kidneys were affected he preferred to open and to drain the bladder for a week or ten days before enucleating the prostate.

Mr. E. C. HORT (London) read a paper on

The Diagnosis of Malignant Disease by Estimation of the Antitryptic Content of the Blood Serum.

He said that the need for improved methods of diagnosing cancer was shown by the fact that of 3532 cases proved after operation or after death to be cancerous the disease had not been recognised in 582 cases—i.e., 1 case in 6 was missed. In 303 cases occurring in the first 25 years of life the disease was not recognised in 128—that is, the disease was missed in 1 case in 2·3. In addition 334 cases diagnosed as cancerous proved to be not malignant. The paper was written to show that it was possible to diagnose cancer by measuring the antitryptic power of the blood serum. By the antitryptic power of the blood was meant the power that a serum had of antagonising in vitro the digestive activity of the ferment trypsin. The antitryptic power of the serum of healthy adults was found to be so constant that healthy serum could be used as a standard. The antitryptic power of the serum in certain non-cancerous conditions, such as after fractures and nephritis, was above the normal as a result of auto-infection; it was also raised in general bacterial diseases. It was raised in 94 of 100 consecutive cases of undoubted cancer; after successful removal of the cancer the antitryptic power of the serum was raised, but in cases in which recur- [illegible] raised power was no proof of malignancy unless simple auto-infection and bacterial infection could be excluded.

Mr. A. B. MITCHELL (Belfast) read a paper on 16 cases of

Perforating Duodenal Ulcer

which he had had under his care. All the cases recovered. He referred to the great frequency of gastric and duodenal ulcers in Belfast, and pointed out that in diagnosing the presence of a perforation too much weight must not be laid on the absence of shock A sudden intense pain and rigid abdominal muscles afforded the most certain signs. Extravasation was not great in amount as a rule, and this he attributed to a contraction of the pylorus, which prevented the contents of the stomach from passing out; and this explanation would account for the fact that the results in perforated duodenal ulcer were much better than those following perforation of a gastric ulcer. He preferred an incision through the right rectus muscle and he closed the opening in the duodenum by means of a purse-string suture. He did not flush out the peritoneum, but he inserted a glass drain tube over the pubes, and from this there always came a free flow of liquid. He preferred to perform immediate gastro-jejunostomy, and this he did in seven cases, all of which recovered. After the operation the patient was propped up in the sitting posture, and a continuous flow of saline fluid into the rectum was set up, about a pint being passed in every hour. For washing out the drain tubes he used a solution of perhydral, about 1 in 10 or 12, and this he found very effective.

Mr. WARD COUSINS said that in his opinion the amount of shock present in cases of perforation depended chiefly on the amount of extravasation.

Mr. W. THELWALL THOMAS (Liverpool) pointed out that Murphy's method of continuous rectal irrigation was often carried out inefficiently.

Mr. MITCHELL, in reply, mentioned an objection to opium even after the diagnosis of perforation was made—namely, that the apparent amelioration produced was likely to make the friends postpone operation.

Mr. G. H. EDINGTON (Glasgow) read a paper on

Some Cases of Intestinal Anastomosis.

He classified these operations into three groups—namely (1) cases in which small intestine was united to small intestine, (2) cases in which the ileum was united to the colon, and (3) cases in which portions of the large intestine were anastomosed. He described some cases which he had treated and gave details of the methods employed.

Mr. C. A. LEEDHAM-GREEN (Birmingham) read a paper on

Scopolamine-morphine Narcosis.

He said that he had some time ago been in favour of spinal analgesia, but it was not an ideal method from the patient's point of view, for a troublesome headache frequently followed. On the other hand, the method which he was now bringing forward was almost ideal from the patient's point of view. At first he gave a large dose of scopolamine and morphine and did not use a general anæsthetic, but it was much better to give a small dose and to follow it with a general anæsthetic. The procedure he preferred was as follows. The evening before the operation he gave ten grains of veronal and this ensured the patient having a good night's rest. Two hours before the operation he injected a sixth of a grain of morphine and a hundred and thirtieth part of a grain of scopolamine. An hour later half of this dose was injected. At the operation itself a general anæsthetic was given, ether being preferred. The advantages were great, because (1) the patient was spared much nervous tension; (2) full narcosis was quickly obtained; (3) the amount of the general anæsthetic was halved; (4) less mucus was formed; (5) a long and peaceful sleep followed the operation, lasting from four to six hours; (6) there was almost an absence of vomiting, for it occurred only in one case out of ten; and (7) the risk was much lessened.

Dr. CLEMENT DUKES (Rugby) said that he thought much of the method and employed it greatly. He found that it was necessary to use a very small amount of the general anæsthetic.

Mr. Leedham-Green said that he did not in any way suggest that the method was final and no doubt it would be improved.

A paper by Mr. Alexander Blaney (Dublin) on

Four Cases of Removal of the Gasserian Ganglion

was read by Mr. H. Stevenson (Belfast). In the paper the methods of removal of the ganglion and the value of the operation were discussed.

On the motion of Mr. Ward Cousins, a cordial vote of thanks for presiding was accorded to Professor Sinclair.

HYGIENE AND PUBLIC HEALTH.

Thursday, July 29th.

President, Dr. Louis C. Parkes (London).

This section met in joint conference with the Laryngology, Otology, and Rhinology Section.

A very full and well-sustained discussion took place upon

Latent Infections of the Diphtheria Bacillus, and Administrative Measures Required for Dealing with Contacts.

Dr. P. Watson Williams (Bristol) dealt with the question from a clinical point of view and Dr. R. M. Buchanan (Glasgow) from a bacteriological standpoint, while Dr. Duncan Forbes (Brighton) and Dr. R. V. Clark (Leeds) dealt with administrative measures.

Dr. Watson Williams, in opening the discussion, said that he considered that if diphtheria was defined as any pathological condition, either local or general, and due to infection by specific diphtheria organisms, it was latent when such pathological conditions were unaccompanied by obvious illness. He further considered that the impinging of diphtheria bacilli on the nasal or oral mucous membrane without any local reaction was not a true diphtheria, but was clinically a form of latent diphtheria. These latent forms could be clinically divided into the following three main groups. 1. Patients who afforded none of the usual clinical indications of diphtheria, were not definitely ill, and yet were found to be anæmic, or to have increased pulse frequency, or who were simply poorly in association with nasal catarrh, membranous rhinitis, faucial redness or slight subacute tonsillitis, otorrhœa, or sores, &c., which on bacteriological examination proved to be diphtheritic. He gave the clinical history of two such cases, one being a patient who presented no clinical symptoms, but whose culture preparation showed diphtheria bacilli and who died shortly afterwards. The second case was one of an adult with accessory sinus suppuration and congested follicular tonsillar crypts, whose culture preparation also showed diphtheria bacilli. A child who came into contact with her showed nothing definite clinically, but a culture taken from it demonstrated diphtheria bacilli and virulence upon inoculation. 2. Cases with local diphtheritic lesions, but presenting no general symptoms of ill health. He considered that this class comprised cases that were indisputably latent. He referred in this connexion to a woman suffering from sore-throat of indefinite nature who three weeks afterwards gave a children's party; some of those who were present developed membranous rhinitis, cultures from whom showed the diphtheria bacillus. After three months they were declared free from infection, and yet they afterwards gave diphtheria to a relative. 3. Persons who presented no local lesions and no departure from normal health, but in whom diphtheritic organisms had been discovered by culture tests. These cases he termed healthy infected contacts. In this connexion the cases cited by Graham Smith, which might appear to upset the speaker's theory, he did not consider conclusive, because no mention had been made of any cultures taken from the nose, which he believed absolutely necessary. He was aware that house surgeons and nurses in contact with diphtheria patients might harbour virulent organisms without manifesting any local signs of disease, but practically they did not convey infection, as organisms inhaled and merely coming into contact with a healthy nasal mucosa were quickly removed, whereas if they were retained and multiplied such cases come under Class 2. He suggested that the practical criterion, however, was the virulence test by inoculation, and that the morphological characteristics of the bacilli were not reliable, and he instanced cases in proof of this assertion. With reference to treatment, he did not think that local applications were of much use in causing the disappearance of the bacilli, though during their use they diminished the infectivity of the patient. It was practically impossible to get any antiseptic in contact with those organisms in the superficial layers of the mucosa and at the bottom of the various crypts in the neighbourhood. He considered that antitoxic serums had some anti-microbial effect, but that in a large proportion of cases they failed because the proportion of bactericidal substances varied, and because it was necessary to use larger quantities of the serum than was necessary merely for their antitoxic effects. Vaccines might be applied locally and cause a diminution in the number of the bacilli; also cataphoresis as employed by Dr. Taylor was worthy of consideration.

Dr. Buchanan said that the identification of the diphtheria bacillus in routine diagnostic work depended on the morphological characters of the organism. The exigencies of the work demanded expedition, which in a small proportion of instances was secured at the expense of accuracy. At the same time, morphology in itself was not sufficient to place the recognition of the bacillus beyond doubt, and for this purpose it was necessary to resort to cultural and inoculation tests involving from four to six days as a minimum period of time. With a view of giving support to bacteriological diagnosis based on morphology various tests had been devised, and the use of media containing different sugars, with an indicator to show the presence or absence of acid production, had given the best results He himself had obtained excellent and rapid results by coagulating ox serum in an equal quantity of water, filtering the mixture, adding 1 per cent. of glucose to one half and 1 per cent. of saccharose to the other half and "tubing," neutral red being used as an indicator. In 24 hours a marked acid reaction was produced in the glucose tube by bacillus diphtheriæ, and in both tubes by bacillus xerosis, while no change was produced in either tubes by the bacillus of Hofmann. The virulence of the diphtheria bacillus in apparently healthy subjects, whether designated contacts or carriers, was only slightly less than the virulence of the organisms in patients. He had applied the virulence test in the case of 21 contacts with positive results in 66 per cent. of the instances. The test as applied to the bacillus isolated from 56 patients showed virulence in 74 per cent. of them. The bacillus diphtheriæ was most tenacious of its virulence, and attempts which had been made to reduce the virulence of the organism by the usual means of heating, drying, and prolonged cultivation had not shown any conspicuous success. On the other hand, it was possible to increase the virulence of a particular strain experimentally. When the bacillus gained a lodgement in the throat it appeared to remain for a varying length of time, whether it produced disease or not. The period of residence of the organism in the sick and in the healthy was probably determined by the same factor and was not apparently influenced by antitoxin. A comparison of clinical cases and infected contacts showed no very marked difference in the average period during which the bacillus was harboured in the throat

Dr. Duncan Forbes, in discussing the question from an administrative point, said that before penal action could be taken a person must be *suffering from* the particular disease, and he suggested that in future legislation the word "suffering" should be replaced by the phrase "in an infective condition." As regards the taking of swabs for bacteriological examination, he considered that too little attention had been paid to the probability of nasal diphtheria being much more infectious than throat diphtheria. In collecting exudation on swabs a careful study should be made of the parts from which it was taken, especially when it was taken from the nose, and where there was much secretion coming from the nose this should be wiped away before applying the swab to the mucous membrane. The administrative measures for dealing with contacts depended on the situation of the primary cases. In schools the first action should be to make inquiries at the school as to absentees from the same class who returned to school shortly before the onset of the disease in the patient. Swabs should be taken from all pupils, present or absent, in whom there was a history of sore-throat or cold. In Brighton infective contacts were sent to the diphtheria wards of the isolation hospital. Except in the case of adults antitoxin was usually injected on admission, and the contact was treated as a diphtheria patient, three negative swabs being obtained from nose and throat before discharge. If objection was made to removal to hospital the child was medical attendant, and children who had been in direct association with case [illegible] who were carriers of Hofmann [illegible] department at the fever hosp[illegible] istrative procedure between Brighton and Bristol was that in the former town Hofmann's [illegible] Dealing with the question of the [illegible] Dr. Forbes said that the [illegible] tions was in order that carrier cases might not be created. It had been proved that antitoxin had no influence on the length of infectivity, though it was probable that attacks of diphtheria in contacts were rendered milder by the injection and were therefore all the more readily overlooked. It thus followed that exten[illegible] the non-isolation of [illegible]

Dr. **Clark** gave [illegible] in Leeds in connexion with outbreaks of diphtheria. He was of opinion that the incidence of cases of latent diphtheria was greatest where contact had been closest. He considered that a bacteriological examination should be made of material taken from the throat of every member of a family in which a case of diphtheria occurred, and that those should be isolated where a positive result had been obtained. The amount of work thus involved would be initially large but would tend to decrease.

Dr. J. A. **Knowles Renshaw** (Manchester) supported Dr. Watson Williams in his advocacy of the virulence test.

Dr. D. **McKenzie** (London) expressed the view that the two lessons to be learned from the discussion were that nasal swabs as well as throat swabs should be taken, and that where Klebs-Löffler bacilli were found in carrier contacts the virulence test should be applied before isolation was resorted to.

Dr. E. W. **Goodall** (London) pointed out that in the epidemic of diphtheria in London in 1893-94 bacteriological examination was not resorted to, and in spite of its absence the disease began to diminish. In order to put himself right with the metropolitan medical officers of health he made it a rule not to discharge patients until a certain number of negative results had been obtained after bacteriological examination, but he did not get any better results than his colleagues who did not follow the same practice. He considered that return cases of diphtheria were a negligible quantity, and he thought that those which were supposed to occur might very well be within the limits of accidental infection. It would be a very good thing if it could be decided once for all whether the swabbing of convalescents was desirable or necessary. The practice of giving prophylactic injections of antitoxin serum was not without danger, and he did not recommend it as a matter of ro[illegible], but sooner or later a [illegible]

Mr. **Herbert** [illegible] with Dr. Davies and Mr. Heaven of Bristol that Hofmann's bacillus might be ignored in the absence of cases of diphtheria, but he considered that during epidemics they must be reckoned with. He emphasised the importance of personal infection and suggested that when a case of diphtheria occurred in a class or group of children instead of prohibiting school attendance altogether the particular class should be taught in the open air.

Dr. **StClair Thomson** (London) asked what should be done with carrier cases, more especially with regard to their treatment. He would like some definite information as to whether treatment with serum shortened the sojourn of the bacilli in the nose or pharynx, and whether it lessened the risk of spreading infection.

Dr. J. M. **Clements** (Batley) referred to the value of the morphological test in determining whether a bacillus was the true diphtheria bacillus or not. For ordinary routine work he found that a microscopical examination after 24 hours' incubation on blood serum was sufficiently accurate. Wesbrook's classification was a useful working one and all bacilli conforming to the C and D types could be safely regarded as positive. The Hofmann type could be disregarded, though occasionally he had met with a virulent case of diphtheria which after repeated swabbings had revealed only that type. The differential culture test which he admitted that owing to the low degree of infectivity of the disease it was difficult to come to any definite conclusion on the matter.

After some remarks by Dr. R. H. **Scanes Spicer** (London) and Dr. H. J. **Egerton H. Williams** (Sheffield),

Dr. **Andrew Wylie** (London) asked Dr. Watson Williams if he would operate on a mastoid or sinus case if the diphtheria bacillus were found in the discharges.

The **President** said that the question under discussion was not one upon which they could dogmatise. He emphasised the importance of taking nasal swabs in suspected diphtheria and said that he had been particularly struck with the large number of outbreaks of the disease in the Victoria Hospital for Children which had been caused by nasal infection. He urged the importance of clearing out the nasal passages with hot water or in other ways before taking material for examination. He agreed with Dr. Goodall that mere contacts should not be sent to hospitals where there were acute cases of the disease. Referring to special homes for carrier contacts he was of opinion that they were quite unnecessary. During inter-epidemic periods he considered the proceeding of little value, but his experience in London had led him to the conclusion that the striking power of diphtheria was much greater in epidemic periods than at other times.

Dr. **Robert Mowbray** (Castlederg) pointed out that the less interference there was with an epidemic the sooner [illegible]ted. The careful guard[illegible] the disease being always [illegible] in an epidemic form.

Dr. **Watson Williams**, replying on the discussion, said that until a few years ago diphtheria was treated in the *ordinary wards of the Royal Infirmary in Bristol, except* in the case of children, and no cases of infection occurred. He considered that carrier contacts in public schools must be isolated, but he admitted that when the organism had been found it was difficult to know what to do with the host. The Hofmann type of bacilli he always neglected. He suggested the advantage of giving antitoxin by the mouth and when administered for prophylactic purposes it might be administered with advantage in peppermint water.

Dr. **Forbes** said that if an outbreak of diphtheria occurred in the scarlet fever ward of a fever hospital under the direct control of the medical officer of health, he considered tha new cases might be admitted to the ward, but that in a children's hospital which would not be under the charge of the medical officer of health he would prefer to close the ward before admitting fresh cases.

Dr. **Buchanan** said that he did not attach any importance to the Hofmann type of bacilli. Routine diagnosis depended entirely upon the morphological test, but where it was necessary to have absolute diagnosis the virulence test was essential. The form of the bacillus depended very largely upon the medium used, and where the morphological test was in doubt a tentative opinion should be given until the virulence test had been applied.

Dr. **Edward Magennis** (Dublin) read a paper dealing with the

Duties of the School Medical Officer.

He deplored the indifference of the public to matters relating to health and expressed the opinion that more attention was [illegible]ings. [illegible] importance of the [illegible] of the section were given an opportunity of inspecting the sewage outfall works of Belfast, situated on land reclaimed from the Lough. Included in the plant were percolating filter beds with revolving sprinklers and Dibdin slate beds, the adoption of the latter having been decided upon in order to avoid the great cost of dealing with enormous quantities of sludge. The difficulties attending the disposal of the sewage of Belfast are associated mainly with the enormous growth of ulva latissima which has accompanied the discharge of the sewage into Belfast Lough. The patient labours of Professor Letts appear to be in a fair way of solving these difficulties, and the visitors saw for themselves the operation of the experiments which had been made.

FRIDAY, JULY 30TH.

Dr. HENRY O'NEILL, a member of the Belfast corporation, in giving a short account of the *Belfast Sewerage System*, said that the problem of the collection, removal, and purification of sewage in Belfast was one of more than ordinary difficulty owing to the large number of linen factories, mills, gas and chemical works, foundries, rope works, and distilleries in the city, and also to the situation of the city on Belfast Lough, the sluggish tides and large areas of shallow water of which seemed to favour the growth of the green seaweed, ulva latissima. The weed when cast up in masses on the beach and allowed to decay and ferment always gave rise to a nuisance. Professor Letts had demonstrated by experiment that if the growth of the weed was to be stopped or even considerably reduced, it would be necessary to produce an effluent free not only from free ammonia but also from those nitrogen compounds such as nitrates, the presence of which in an effluent was usually regarded as evidence of *purification.* Experimental contact beds had been found (when dealing with sewage which had previously undergone screening and about six or eight hours' septic-tank treatment) to give an effluent containing comparatively small quantities of nitrogen in any form, but these beds rapidly silted up. Percolating filter beds with revolving sprinklers were proved to be highly satisfactory, both as regards economy of space and freedom from silting up. The effluent produced, though an exceedingly good one from the point of view of purification, contained a large quantity of nitrogen as nitrates, which it was recognised would provide an undesirable amount of food for the ulva. It had been finally found by Professor Letts that by mixing the effluent from a percolating filter with sedimented sewage in about equal quantities and again treating the mixture on contact beds, the organic matter in the sewage was oxidised at the expense of the nitrates in the filter effluent, the net result being a reduction in the total quantity of ulva-growing pabulum

Professor E. A. LETTS (Belfast) said that during the past ten years he had been engaged in investigations with the object of arriving at the most suitable *Scheme of Purification for the Sewage of Belfast* and its effects on the waters of Belfast Lough. He first of all described the special conditions obtaining in Belfast and Belfast Lough. At one time the sewage of the town was discharged into the river through several outfalls, with the result that the river grew exceedingly foul, its bed became coated with black and highly offensive mud and its water turbid, while the stench at low tide and in warm weather was most offensive. The seaweed, consisting principally of ulva latissima and different species of enteromorpha, caused a considerable nuisance when washed ashore. A new main drainage scheme was begun in 1889 and included two main trunk sewers in the city discharging their contents only on the ebb tide. The condition of the river rapidly improved with the completion of this scheme, but the seaweed nuisance assumed such serious proportions as to demand public action. As a result of such action being taken a joint board was formed of the sanitary authorities concerned for the purpose of abating the nuisance by removal of the seaweed as it was cast ashore. The enormous cost of this procedure led to its abandonment and experiments were carried out by him with a view to preventing the growth of the seaweed. The details of these experiments were placed before the section in a very graphic and lucid manner by Professor Letts, who stated that the results were such as had been given by Dr. O'Neill in his paper.

Dr. R. J. EWART (Liverpool) assistant medical officer of health for Middlesbrough, presented a contribution dealing with some features concerning the *Sewage Pollution of the Tees Estuary.* After describing the formation of the estuary and giving a short account of the changes which had taken place during the past 25 years, not only in its configuration but also in the methods of disposal of the local sewage, water carriage having been adopted, he gave the results of bacteriological investigations which he had made in connexion with cockles and mussels collected from the banks of the estuary. The mussels were collected, 50 or 100 at a time, from all parts of a bed and indiscriminately taken as regards position, those under one and a half inches being discarded. They were taken immediately to the laboratory and scrubbed in sterile water, the hands of the investigator being covered with sterile rubber gloves. It was found that bacillus coli slowly became overgrown by the commoner organisms, and that the process was less rapid at the lower temperatures than at the higher. Bacillus typhosus showed much the same viability except that its periods were about halved, and under ordinary conditions it was usually overgrown in a week. The conclusions which Dr. Ewart came to as the result of his investigations were that it was possible to obtain mussels free from all evidence of sewage pollution; that there was a close relationship between size, number, and sewage pollution, for it appeared that where the mussels were of sufficient size to be marketable and were in sufficient quantities to be worth gathering, evidence of pollution was marked. He further found that the number of bacillus coli in the mussels corresponded closely to the environment, so that the mussel could not be regarded as a filter accumulating harmful organisms; the mussel did not seek these organisms, they were, so to speak, thrust upon it. Broadly speaking, a fall in the proportion of organisms growing at 20° C. compared with those at 37° C. corresponded with sewage pollution, and the same might be said of spore-bearing forms. He considered that mussels could not be looked upon as safe, especially when it was remembered that they were apt to die in transit to inland towns, in which case the bacterial contents would rise by millions. He concluded by discussing the forms of illness which might arise from eating mussels. He divided them into two classes. The first he called "toxic," as being due to the absorption into the system of organic poisons present in the substance of the mussel itself, and the second "bacterial," which he subdivided into general and specific infections.

Professor DUNBAR (Hamburg) said that the treatment of sewage effluents in tidal waters had at one time been considered an easy task, and only lately it had been realised that danger would arise from turning crude sewage into tidal waters. Greater importance had of late years been attached to the question from the fact that epidemics of typhoid fever had occurred through the consumption of shell-fish taken from waters into which sewage had been discharged. Sewage must be treated so as to kill all pathogenic organisms. This was formerly thought to be quite easy, but it was now known that it was impossible to disinfect crude sewage. In Hamburg after the great cholera outbreak of 1892–93 it was considered necessary that the sewage of the town should be sterilised, and with this end in view proposals were made to add lime to the crude sewage. The cost of adding lime in the proportion of 1 part to 1000 of sewage would be very great, and as it was impossible to kill bacillus typhosus even with 1 part in 500 the cost would be prohibitive. Crude sewage could not be disinfected. Bacteria coming from the intestine were found to be wrapped up in mucous matter, and the difficulties attending disinfection could be overcome by septicising, but for this purpose very large tanks were necessary, so that the question was whether it would not be cheaper to purify before disinfecting. In Hamburg all sewage coming from fever hospitals and emigrant stations as well as the waste water from the Hygienic Institute and disinfecting plants was disinfected. Where typhoid fever patients were nursed in their own homes official disinfectors were sent who explained the importance of, and the mode of, disinfecting the discharges.

Dr. W. J. WILSON (Belfast) gave an explanation of the working of an ingenious apparatus, which he showed to the meeting, for isolating bacillus typhosus from drinking water.

Sir PETER O'CONNELL (Belfast) said that the existence of differences of opinion on the question under discussion was evidence of the difficult nature of the problems to be solved. The most important fact to bear in mind was that the science of sewage purification was well able to deal at no prohibitive cost with the sewage of a town even as large as Belfast, and of turning out an effluent as pure chemically as many waters used for domestic purposes, but this very effluent on account of its purity was undesirable where local circumstances favoured the growth of seaweeds.

The PRESIDENT assured Professor Dunbar that the difficulties connected with the disinfection of crude sewage were fully realised in Ireland. He pointed out that they were not alone scientific difficulties, but those associated with storm overflows, for it would be of little use to disinfect the sewage to the neglect of storm water. He spoke with approval of the steps which were being taken in Hamburg to destroy infective organisms. He asked Professor Letts whether he had made any experiments as to the efficacy of sulphate of copper in the destruction of ulva latissima.

Professor LETTS replied that he had experimented in that direction and had found that a very small proportion of sulphate of copper did kill the ulva. He had calculated that the cost of an experiment on a practical scale would be about £500, and he thought it was well worth considering whether two or three doses might not be effective if applied at the proper season. While agreeing with Professor Dunbar as to the difficulties of disinfecting sewage before it was discharged into a river, he pointed out that crude sewage was a source of danger in localities where bathing was indulged in.

Dr. T. CARNWATH (Manchester) said that in connexion with the question of oyster and mussel contamination two facts should be [illegible] of bacillus coli [illegible] sewage pollutio[illegible] Viallanes had found that when mussels or oysters were placed in water which had been made turbid they rapidly rendered it clear by a peculiar process of filtration. It had been also found that the amount of water which could be filtered in this way per hour by the Portuguese oyster was 5·5 litres, by the mussel 3 litres, and by the French oyster 1 litre. A mussel would thus "absorb" or "ingest" in the space of one hour the organic matter, and incidentally sewage bacteria, if such were present, contained in three litres of water. It might be expected, therefore, that a considerable number of bacillus coli communis would be found in the mussel, but his observations had shown that although the mussel from its mode of life was exposed to considerable risk of infection, it did not when healthy furnish conditions favourable to the multiplication or survival of the organism. There was, indeed, sufficient evidence to show that the conditions were distinctly unfavourable. If infected mussels were placed in pure water they gradually rid themselves of bacillus coli, over 99 per cent. disappearing within the first few days. A quarantine period of even a week would be sufficient to reduce the number of organisms enormously, so that the risk was also lessened of the mussel serving as a means of transmission of occasional and much less resistant pathogenic organisms such as bacillus typhosus or the cholera vibrio.

The PRESIDENT said that they would no doubt be in [illegible] shell-fish being [illegible]. Safety to the [illegible] before its consumption in pure water.

Mr. P. C. COWAN, M.Inst.C.E., engineering inspector to the Local Government Board for Ireland, expressed his gratification at the possibility of an early solution of the Belfast sewage problem. If the inhabitants were becoming impatient at the length of time which had been taken in arriving at that solution they must recognise, as Professor Dunbar had pointed out, that modern problems in connexion with the purification of sewage were of extreme complexity.

Dr. J. J. PATERSON, assistant medical officer of health of St. Helens, in a paper dealing with

Measles in Schools,

[illegible] of children day by day from [illegible] bringing them into close con[illegible] were eminently favourable to the rapid propagation of infectious disease, but at the same time, with efficient administration, those very conditions [illegible] with a widespread outbreak of measles which occurred early in the present year. Those measures had for their key-stone a section of a private Act which required teachers in public elementary schools in St. Helens to notify to the medical officer of health any cases of infectious disease occurring among children under their charge. The exclusion of centres of infection was thus rendered possible, but in spite of prompt exclusion it was found in the end necessary to close the infant departments of a large number of schools in the town. This failure to stop the epidemic by means of individual exclusion was mainly due to the want of intelligent coöperation of [illegible]ation of infected children. Dr. [illegible] opinion that much might be done [illegible] this direction by the adoption of systematic home visitation by a capable health visitor.

Dr. D. J. MACKENZIE (Glossop) said that he regretted the deletion of Article 101* from the Code, for an entire school had now to be closed in order that the Government grant might be obtained. He was of opinion that where measles had taken hold in a school there was little possibility of stopping its spread. He pointed out that in Austria-Hungary when one or two cases of the disease occurred in a class that class was closed for a period of two weeks. He considered that the reason why adults were not attacked was because they were immune from having had the disease in childhood.

Dr. W. T. BROOK FOX (Blyth) said that, as in so many other public health matters, the financial side bulked too largely, and that was one reason why there was in so many districts compulsory notification of erysipelas but not of measles. It was often only when the Government grant was imperilled that a school was closed. He expressed the opinion that there was an increasing tendency among parents to isolate the children who were infected, even before medical advice had been sought.

Mr. HERBERT JONES (Hereford) said that it was very unsatisfactory to find that even after the adoption of the admirable administrative measures detailed by Dr. Paterson, resort in the end had to be made to the clumsy practice of closing large departments of the St. Helens schools. He pointed out that there were two methods of isolating an infected person—one in which the patient was kept apart from those who were well and the other in which the uninfected were kept away from the infected. The latter method he had carried out in the Rhondda Valley and in Herefordshire by displaying in an infected house a card on which was printed in large type the name of the particular infectious disease concerned, and a request that no person should be admitted to the house except the regular occupants or those whose services were absolutely needed.

Dr. A. WALKER (Edinburgh) said that in Edinburgh there was a tendency to organise a crusade against the notification of infectious diseases, and care should be taken not to push measures of control too far. Special attention should be paid to the closing of schools at the earliest possible moment. He looked forward to the time when they would be able to lay by the heels the very illusory microbe of measles, for there was at present no evidence of the precise prodromal period of the disease. He congratulated Dr. Paterson upon having given a very useful and practical paper on a not very grateful subject.

The PRESIDENT said that the exposure of warning cards as suggested by Mr. Herbert Jones was likely to be resented in many districts.

Dr. PATERSON, replying on the discussion, said that closing a school during the incubation period was not effective in a very general epidemic on account of "mixed crops" or crops occurring at irregular intervals, and because of re-infection after opening the school. He emphasised the importance of preventing young children from becoming infected.

Dr. A. W. GILCHRIST (Nice) read a paper on the

Endemicity of Influenza,

in which he stated that a disease generally recognised as influenza had prevailed continuously over a wide extent of the civilised world during the past 20 years. Although bacteriologists had failed to assign a distinct specificity to the disease, there was no doubt as to its being susceptible of clinical characterisation and recognition. He pointed out a certain number of general analogies between tuberculosis and influenza and expressed the opinion that it was incumbent upon those responsible for the public health to inquire into the conditions which were presiding over the transition of influenza from the pandemic and epidemic into the endemic stage.

Dr. J. B. STORY (Dublin), in a paper on the

Neglect of Physical Education in Primary and Secondary Schools,

called attention to such neglect in the schools in Ireland and pointed out that in other countries, notably in Sweden and Germany, the State had made regulations for physical education. He animadverted on the fact that upon neither of the boards of education in Ireland was there a representative of the medical profession as such. The two medical men who happened to be on the boards were there [illegible] tives of rival collegiate institutions. He [illegible] appointment of direct medical representatives.

PSYCHOLOGICAL MEDICINE.

THURSDAY, JULY 29TH.

President: Dr. T. OUTTERSON WOOD (London).

Dr. A. T. SCHOFIELD (London) read a paper on

The Present State of Medical Psychology.

He contended that the idea of the scientific use of the mind in disease by either the medical practitioner or the patient had hardly as yet in this country entered the sphere of serious medical thought, although everywhere on the continent of Europe and in the United States of America it was scientifically studied and seriously discussed. He asked whether it was in accordance with enlightened views or sound practice in medicine that a subject so fraught with powers for good and evil, which were everywhere used, should be nowhere taught He then handed in returns which he had obtained from our 42 leading universities and schools of medicine in Great Britain and Ireland. The following were the three questions sent. 1. Have you any lectures on psychology other than those on insanity? 2. Have you any means of instruction on psycho-therapeutics or the use of the mind in medicine? 3. Have you any text-book in use on this subject? The answers received were so largely in the negative that it was quite clear that this subject formed no part of the ordinary medical curriculum. There were one or two brilliant exceptions in some of our larger schools, which showed, however, that a beginning was being made. Dr. Schofield then proceeded to remark that, although there were many optional subjects of medical study, if they were not learnt at any rate they were not practised. With psycho-therapeutics, however, it was not so, for whether he wished it or not *the physician's personality reacted powerfully upon the* patient, and though nowhere studied psycho-therapeutics was unconsciously practised. The eight leading psychic forces operating between the medical practitioner and the patient were then enumerated and the force and action of each were stated. *They were, in brief, the practitioner's reason,* emotion, and will, the same attributes in the patient, and the physical and psychic environments. Many illustrations were given of the power of the mind over the body in disease, and the paper concluded with two considerations showing the urgency of the subject. The first was the rapid increase of functional nervous diseases in which, of course, this treatment was peculiarly successful, as lately pointed out by Professor William Osler in urging the general teaching of psycho-therapy. The second consideration was the enormous increase of quackery in the centres of civilisation. Dr. Schofield quoted the concluding sentences of a leading article in the *British Medical Journal* which stated that the only way in which quackery could be destroyed was the production of an intellectual soil in which it could not grow, and it was for this soil that he pleaded, and asked that mental therapeutics might form a part of the ordinary curriculum of every medical student.

The paper was supported by Dr. T. D. CROTHERS (Hartford, U.S.A.), Dr. HELEN BOYLE (Brighton), the PRESIDENT, and others.

Dr. C. A. MERCIER (London) contributed a paper entitled

Somatic Delusions and Local Lesions.

In this paper, which was read by the honorary secretary, Dr. Mercier related the case of a man, aged 36 years, formerly a clerk, who had a persistent delusion to the effect that his bowels were obstructed. He frequently refused food on the ground that it would never pass from him. His abdomen was shrunken and his bowels were moved several times a week. He had also one other delusion—namely, that he had been ravished per rectum by a foreigner, and he further imagined that he had in this way contracted syphilis, which he regarded as the cause of his obstruction. The delusions existed for years. He occasionally did a little work, but he spent his time chiefly brooding over his misery. As he lost flesh, in spite of copious feeding, his chest was examined, whereupon consolidation of the whole of the left lung was revealed, although there was an absence of the usual symptoms. After two years' illness he died, apparently from exhaustion. At the necropsy the stomach and duodenum [illegible] found healthy, but the remainder of the small intestine [illegible] diseased, the solitary glands projecting as dark red succulent-looking nodules, with a certain amount of ulceration. The ulcers were circular, the largest about the size of a sixpence, one of which had perforated and caused peritonitis. The large intestine was normal, but on the posterior wall of the rectum, four inches above the anus, there was an irregular ulcer of the size of half-a-crown, demonstrating the unmistakable existence of recent tubercle. The liver appeared normal, but behind and below the right lobe there was a spherical tumour of the size of a cricket ball enclosed in a glistening capsule On section its contents were caseous. The left lung was consolidated and riddled with cavities. The right lung was emphysematous and displayed miliary tubercles. The brain and other organs appeared normal. This case was a good instance of the difficulties that attended the recognition of bodily diseases among the insane. There were no pulmonary symptoms, neither were there abdominal pain or other indications of the peritonitis from which the man died. It would appear that the character of the delusions was connected in some way with the seat of the local lesions. The delusion that his bowels were obstructed corresponded with the fact that the intestines were diseased. The delusion that he had been ravished per rectum corresponded with the existence of a large ulcer in that part of the bowel. A crude hypothesis would be that the bodily disease was the cause of the delusions, but ulceration of the intestines was frequent enough without any concomitant delusion, and the lung was much more completely diseased, yet no delusion was referred thereto. A more plausible hypothesis would be that the cœnæsthetic sensations from the diseased bowel determined the localisation and character of the delusion in a person predisposed to insanity, or actually suffering from mental disorder. Many insane persons, however, were the subjects of gross disease, and yet it was rare to find that the delusions had a reference to a diseased organ. There was no reference of this patient's delusion either to the lung or to the large abscess, which probably at one time had been active, neither was there any reference of the delusion to liver or loin. There was evidence of long-existing disease as well as recent disease, but the facts seemed insufficient to warrant the assumption that such disease coloured the delusions. A third possible causal connexion between the delusions and the intestinal lesions offered itself. He (Dr. Mercier) had long insisted on the existence of a trophic function of the cerebral convolutions and on the disturbance of metabolism, sometimes widespread and shallow, sometimes restricted and profound, that attended that disorder of the function of the convolutions which was otherwise manifested in insanity. Insane persons appeared to become starved to death from incapacity of the tissues to assimilate nourishment in spite of being fed abundantly. The condition of the skin and its appendages was a frequent example in chronic insanity. Insanity consisted of disorder of conduct, disorder of mind, and disorder of metabolism, but these three were seldom proportionate to one another. The metabolic disorder in insanity was sometimes strictly localised. He had recorded a case in which all the nails of both fingers and toes were shed after an attack of acute insanity. It was common knowledge that the nutrition of tissues might be seriously disturbed by disorder of the ganglia from which their nerve-supply issued, as exemplified by the eruption of herpes, the acute bedsore of special disease, and the glossy skin of hemiplegia. He contended that the highest centres as well as the lowest and middle ranks of nerve centres exerted a trophic function. The circumstance that the delusions of the patient already mentioned had direct reference to his bowels was evidence, in Dr. Mercier's opinion, that the derangement affected with greater severity that portion of the cerebral convolutions in which the bowels were prominently represented Following the opinion of Dr. Hughlings Jackson that in every part of the convolutions the whole body was represented, but that it was not uniformly represented, it might be supposed, though not yet proved, that there was predominant representation of the viscera Moreover, it might well be that one viscus had predominant representation in one part of the area and another in another. In the case of this particular patient the area of convolutions most gravely disturbed was that in which the viscera were represented, and more especially in that portion in which the bowel was *predominantly represented. The derangement of function* did not appear to spread widely, for there was but little disorder of mind or conduct beyond that which had reference to the bowel. The hypothesis that most commended itself to him was that the structural disease of the bowel was secondary to and consequent upon the derangement of function of the cerebral centre in which the bowel was predominantly represented. He suggested that the nutrition of the bowel was so lowered that it fell an easy prey to the tubercle bacillus and resulted in the tuberculous ulcers. The existence of a local lesion in every case of somatic delusion was not necessitated by this hypothesis. In the case in question the lesion required as much the existence of the tubercle bacillus as it required weakness of the bowel for the bacillus to act upon. Tuberculous ulceration of the small intestine was not common and of the rectum very uncommon. These organs, unlike the lungs, were highly resistant to the tubercle bacillus and needed some very special preparation to render them vulnerable. Even supposing that no organ could, until its metabolism were lowered and damaged, become a prey to the tubercle bacillus, it was certain that the failure or alteration of the nerve-supply from the convolutions was not the only condition of such failure of metabolism, so that the absence of delusion referred to the lung did not militate against the hypothesis. This last hypothesis, strange as it at first appeared, satisfied the facts of the case and was not inconsistent with our general knowledge of the operations of the nervous system, and to this he ventured to commit himself.

The PRESIDENT congratulated the section on hearing the valuable paper from Dr. Mercier, who, he regretted to say, was absent on account of ill-health.

Dr. W. R. DAWSON (Dublin) said that he was much interested in the hypotheses advanced in the paper. He was inclined to think that diseases occurring in persons of a suspicious or morbid temperament might be productive of insane delusions. He described a case of recurrent melancholia that came under his observation from time to time. The patient in question had some slight affection of the nose, which was magnified during his attacks of depression into a delusion the insane nature of which he appreciated when he recovered. Dr. Dawson said that he was not so certain of the trophic influence of the cerebral convolutions, and that even some doubt had been expressed on the trophic functions in the lower centres, as instanced in some experiments on a dog with division of the spinal cord. He quoted Professor James's theory of the emotions as bearing on the subject, and to some extent controverting the third hypothesis to which Dr. Mercier committed himself.

Dr. G. E. SHUTTLEWORTH (London) read a paper on

Mongolian Imbecility.

He said that the subject of so-called Mongolism had attracted attention, in consequence of the recent publication of papers by Dr. W. Bertram Hill, Professor Sante de Sanctie of Rome, Dr. Meltzer of Waldheim, and Dr. Babouneux of Paris, as well as in consequence of an exhibition of 14 or 15 cases at the Royal Society of Medicine. The material upon which his paper was based consisted of about 350 cases, a fair proportion of which he had previously seen, in the course of his official connexion with the Asylum for Idiots at Earlswood, the Royal Albert Asylum, and the imbecile institutions of the Metropolitan Asylums Board, as well as in private practice To the medical officers of the institutions mentioned (and to others) he was indebted for up-to-date particulars and statistics, and especially to Dr. D. W. Hunter, assistant medical officer at the Royal Albert Asylum, Lancaster, for a valuable collection of illustrative photographs. After glancing at the history of the subject and suggesting that till within the last 40 or 50 years the Mongolian type of imbecility had been confused with cretinism, he said that the credit of pointing out the distinctive features of this type was due to Dr. John Langdon Down, who in 1866 propounded a theory of ethnic degeneration occurring in children of European parentage, of which the Mongolian was the most striking instance. The facial aspect with obliquely placed palpebral fissures, squat nose, fissured lips and brachycephalic head, furnished with sparse wiry hair were some of the points of resemblance to the Mongol or Kalmuck characters, though there was an absence of the high cheek bones so marked in the latter. Curious abnormalities of hands and fingers were seen in Mongolian imbeciles, *although they did not exist in real Mongols.* However, the resemblance to these Easterns was sometimes so striking as to suggest to the lay mind the *sobriquet* of "John Chinaman" as appropriate to a feeble-minded boy of this special type. The type was a fairly common one amongst imbeciles in England. Dr. R. L. Langdon-Down said that it was seen in 10 per cent. of his cases, and in the large English institutions it figured in about 5 per cent. of the inmates. The frequency of the type was probably less in France, Germany, and Italy, but in Scandinavian countries and in some, at least, of the American institutions for the feeble-minded it was as great as in England. With regard to the etiology of this condition, it seemed likely from the institution and other statistics in his possession that the preponderant causative factor was the reproductive exhaustion of the mother, who in a large proportion of cases were approaching the climateric, and in others was debilitated by illness, &c., during pregnancy. Mongols were in a majority of cases the last children of long families; occasionally, however, they were the first-born, procreated at a time when (as Dr. G. F. Still has suggested) the reproductive function of the parents might not have been established in full vigour. Dr. Shuttleworth cited numerous figures as supporting the above views—e.g., at the Royal Albert Asylum the mothers of 41 Mongol children out of 120 tabulated cases were over 40 years of age, and out of 107 tabulated 68 appeared to be last born children and 12 to be first-born; at Earlswood 46 out of 98 Mongols were stated to be last-born. As already mentioned, 41 mothers of Mongols out of 120 cases at the Royal Albert Asylum were over 40 years of age; of these mothers, one was stated to be 47 years of age, three to be 46 years of age, *and six to be 45 years of age at the date of birth of the* Mongol child. Statistics differed as to the influence of neuropathetic heredity in these cases. Dr. Hjorth and Dr. Carson traced but little in their cases. At Earlswood it was stated to exist in about 25 per cent. Personally Dr. Shuttleworth, forming his judgment on private rather than on institutional cases, was inclined to attach considerable importance to this factor. With regard to the etiological *influence of parental syphilis, his experience did not coincide* with Dr. G. A. Sutherland's experience, that it was a frequent factor, and the statistics of the Royal Albert Asylum, of the Keller Institute, and of the Eastern Counties Asylum lent no support to that view. Dr. Shuttleworth had not been able to trace many cases to parental alcoholism, though maternal alcoholism might well prove to be a causative factor. With regard to family history of tuberculosis. formerly considered a frequent cause, his present statistics did not confirm the view he formerly held, that the taint [illegible] as compared with o [illegible] to tuberculous disea [illegible] was inclined to think, however, that any depressing influence, toxic or otherwise, affecting the mother during generation might tend to the production of "Mongol" offspring. Amongst the anatomical peculiarities which characterised the class Dr. Shuttleworth mentioned brachycephalism, [illegible] normal, thus differing from cases of sporadic cretinism. Macroscopically the brain, which was often of fair weight, had coarse convolutions, with deficiency of secondary convolutions, and annectant gyri, the sulci being shallow, and microscopically Bourneville had remarked "rarefaction of cells" and thinning of the fibres of the Exner net. As with the physical so also was there a resemblance of mental characteristics, such as general backwardness of development, want of originality, but remarkable imitativeness. This latter quality was an aid in training, and, as a rule, Mongolian imbeciles, excluding of course low grade cases, were capable of some amount of education, and even of some degree of industrial usefulness of a simple mechanical kind. But (as [illegible]

imbeciles, owing *to their proneness to invasion by tubercle,* especially about the age of puberty. Their conclusions might be briefly summarised as that of permanent "immaturity."

Dr. R. L. LANGDON-DOWN (Hampton Wick) showed some interesting print impressions from the hands of Mongolian imbeciles, the chief lines being two in number instead of the usual three. The deficiency of stature he estimated as due to the short neck and proportionate decrease in the length of the extremities as compared with other imbeciles. He regarded the condition of the jaw and palate as being accentuated by mouth breathing, which was common. He frequently found that Mongolian imbeciles were born after a prolonged rest from child-bearing.

Dr. C. CALDECOTT (Redhill) referred to the fact that most Mongols died before the age of 20 years. In his experience at Earlswood he had only seen four cases over that age, and then the characteristics tended to disappear. In the records of the 158 cases that had died there were only two in which any doubt existed as to tubercle being the cause of death. He considered that thyroid treatment in these cases was highly detrimental.

Dr. SHUTTLEWORTH, in reply, said that he did not find tubercle quite so rampant in private practice in these cases, but admitted that Mongols were prone to invasion by tubercle and frequently died therefrom.

FRIDAY, JULY 30TH.

Dr. W. R. DAWSON (Dublin) opened the day's discussion with a paper entitled

"*Considerations upon the Report of the Royal Commission on the Care and Control of the Feeble-minded.*"

He said that in his opinion the state of affairs revealed by the investigations of the Royal Commission was exceedingly unsatisfactory. Even in England it was found that 0·83 per cent. of the population suffered from mental abnormalities of some form or other, of whom a considerable proportion—about a fourth—required immediate provision; whilst in Ireland the proportions both of mental defect and of undealt-with cases were much larger. There was, therefore, urgent need that some attempt of an organised and coördinated kind should be made to deal with the whole class of mental defectives. In considering the problem before them the fundamental idea adopted by the Royal Commission was the duty of the State to protect all persons who were prevented by mental defect from taking part in the struggle of life, and to include their property within the scope of its protection. The work had to some extent already been performed by a number of different agencies, but the Poor-law authorities had been paramount in dealing with the uncertified cases in the lesser degrees of mental defect. The evidence showed that the Poor-law had been most inefficient in this connexion; that it was mental defect and not any social circumstances arising therefrom which constituted a claim on the commonwealth; and that the very varied character of the different classes of defect and the highly special nature of the methods of dealing with them rendered it essential that these cases should be in the hands of a special department, with a strong central authority directing, controlling, and coördinating the whole. He was in hearty agreement with this conclusion of the Royal Commission and with the view that the central authority should be primarily medical. The peculiar social consequences of mental defect rendered it necessary that there should be close coöperation between the judicial and administrative authorities, and therefore the amalgamation of the Lunacy Commission with the Chancery Visitors in forming the central authority seemed to be justified. The Royal Commission desired to retain as local authorities the present county councils, while checking any retrograde or undesirable tendencies on the part of these bodies by the power of the central authority. The management of the institutions, he considered, might be left in their hands subject to certain restrictions, but the asylum medical service should be turned into a State service on similar lines to those recommended for the Irish Poor-law medical service, whereby it was suggested that the appointments should be made by a central council as the result of examination, and that the salaries of the medical officers should be paid from Imperial funds, leaving the management in other respects in the hands of local bodies. Regarding the detailed recommendations he thought that some were open to question. Thus he doubted whether "oversight"—which apparently was equivalent to registration only—or even certification would be of any use apart from detention in providing care and control. He accepted with some criticism the change in nomenclature, substituting the terms "mentally defective" and "hospital" for "lunatic" and "asylum." The history of the institutional treatment of insanity showed a continual effort to mitigate the unpleasant sound of the terms used in connexion with it. The classification of the mentally defective into nine groups he deemed unnecessarily elaborate. Thus the separation from the class of "persons of unsound mind" of "those whose mental abnormality happened to be due to age or decay of their faculties" was devoid of utility. Likewise the moral imbeciles and mentally defective epileptics, inebriates, and deaf and dumb, or blind, might be merged with the other idiots, imbeciles, and feeble-minded. Thus four classes would suffice—viz., "persons of unsound mind," "idiots," "imbeciles," and "feeble-minded," the last three differing only in degree. The constitution and powers of the central authority seemed upon the whole satisfactory, especially the preponderating importance assigned to the medical element and the provision for increased inspection. Those at present connected with the Chancery Division apparently were opposed to amalgamation, but it was to be hoped that their objections would be overruled in the promotion of what it was proposed to call the Board of Control, which might be developed in Ireland as well as in the sister countries. He advocated the appointment of assistant Commissioners and also that of certifying medical practitioners, the latter to act on behalf of the county councils. Experience had taught him that it was far less easy to decide upon the status of a case of feeble-mindedness than was usually supposed, and that with the increased work thus created a special body of practitioners would be required. He questioned the procedure as regards the adoption of plans and estimates for buildings as being cumbrous and involving undue expense and delay. The submission of plans and estimates first to the Board of Control, next to the Local Government Board, next to the Secretary of State, and finally back to the local authority, was surely unnecessary. He agreed with one of the Commissioners in his objection to the system of compelling medical practitioners and other public officials to notify to the local authority all cases of mental defect coming to their notice, unless public assistance was required. Such a procedure was too inquisitorial and would give rise to friction in practice. He approved of the suggestion that patients liable to frequently recurring attacks such as would be likely to relapse should be reported on and dealt with specially. In connexion with the admission of patients he approved of Dr. J. C. Dunlop's objection to the proposal that the judicial authorities should be given some discretionary power as to the method of disposal of mentally defective persons. He regarded the intervention of the judicial authority as unnecessary in the great majority of cases. In Ireland there had never been intrusion of the judicial element as regards paying patients and no disadvantages or abuses had arisen from its absence. It, moreover, tended to getting patients under special treatment in the early stages and thus promoting their recovery. He urged that the difference existing in Ireland as regards procedure for public and for paying patients should be retained if the judicial authority was really indispensable for the former. The recommendations that the education and training of defectives be removed from the control of the ordinary education authorities received his approval. He also urged the desirability of creating special classes rather than special schools in the first instance. He believed that in Ireland, at all events, much greater difficulty would be experienced in getting parents to send their children to the latter, while the former had advantages in the case of transfer of pupils to and from the ordinary classes. The recommendations regarding the criminal and inebriate and epileptic mental defectives might be accepted. He also concurred in the advice that institutions for sane epileptics should be under the same control, and he ventured to suggest that the institutions and homes for sane inebriates might also with advantage be placed under the same control. He had hoped to find the system of family care in the treatment of the mentally defective more highly recommended. The value of this system, so easy of introduction, so elastic, so successful wherever fairly tried, and so inexpensive, had escaped proper recognition. He considered the report a monument of industry and a mine of information, and said that it should awaken the nation to the existence of its mental defectives and should promote legislation for their proper care and control.

Dr. SHUTTLEWORTH (London) referred to the history of the Education Act of 1899, which was legislation for defectives not to be graded under the Idiots Act. It failed, however, as being permissive only and not compulsory, and the result was that probably only one-third of the cases were dealt with by the authorities. Moreover, the defectives on reaching the age of 16 years had no authority to care for them. He objected to classing cases of feeble-mindedness of a mild character under the general heading of mental defectives, which in its modern connotation was to include lunatics. He thought it might prevent parents from consulting their medical attendants from fear of official interference. He also mentioned that many children, although subnormal at the age of six years from immature development, were quite normal at the age of eight years, and that they would needlessly be classed with mental defectives.

Dr. W. J. MAGUIRE (Belfast) said that speaking from the physician's point of view he hoped that wards would be set apart for mental cases in the general hospitals. There was at present only one institution for imbeciles in Ireland—namely, the Stewart Institution, with 100 beds. Places were needed where mental defectives could earn their living under supervision.

Mr. P. J. FAGAN (Dublin) said that he spoke as one of the inspectors of reformatories in Ireland, having under his cognisance about 8000 children, taken from the waifs and strays of society. He referred in terms of approval to the Government offer to increase the grant from 5*s.* to 7*s.* per week for mental defectives, which would enable the managers of schools to deal with the whole group adequately. Many cases, coming as they did from a miserable environment, required practical training rather than book knowledge and were improved thereby.

Dr. E. C. BIGGER (Dublin) said that his experience as a Poor-law inspector taught him that Ireland was behindhand in the care of the feeble-minded. Many, he considered, might become good citizens if properly looked after in early life. While so much was being done in asylums, too little was done in preventive measures.

Dr. CALDECOTT spoke of the work achieved at the asylum for idiots at Earlswood during the past 60 years. All types of feeble-mindedness from the minor to the deeper grades were received at that institution. He considered that its special schools and shops were even better than those of the London School Board. He deprecated certain of the recommendations as tending to curtail voluntary effort and he thought that the financial considerations had been greatly under-estimated.

Mr. C. S. MORRISON (Hereford) expressed a hope that what was at present voluntary in the Education Act for defectives should with future legislation become compulsory.

Dr. J. M. MACCORMAC (Belfast) stated that he saw many cases of incipient insanity at the hospital for nervous diseases, and he considered that many cases might be saved if taken proper care of in early childhood.

The PRESIDENT commented on the difficulty experienced in providing for the large group of the uncertified mental cases and regretted that no proposals had been submitted by the Royal Commission for dealing with the ordinary inebriate, who was commonly regarded as sane yet was incapable of taking care of himself.

Dr. DAWSON, in his reply, estimated that there were about 10,000 mentally defective children in Ireland for whom at present there was no provision.

The PRESIDENT, in terminating the proceedings, expressed the gratification of the section at the presence in it of Lady Aberdeen, who had done such good work in connexion with tuberculosis amongst the poor in Ireland, and he trusted that she would extend her sympathetic help in the alleviation and better care of the mentally defective, which was a question of national importance.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

THURSDAY, JULY 29TH.

President, Dr. STCLAIR THOMSON (London).

Dr. P. WATSON WILLIAMS (Bristol) gave a demonstration on the cadaver of his modification of Killian's radical operation on the frontal sinus and ethmoid cells. He showed the different stages of the operation and demonstrated the steps as he proceeded, pointing out the dangers of entering the cranium through the olfactory plate, and the means of avoiding them, which his operation afforded, by giving a full view of the whole field and by keeping external to the middle turbinate. The operation consisted in the formation of an osteoplastic flap which was turned outwards to enable the interior of the nasal passage to be seen and treated accordingly. The ethmoidal cells could be removed and no pockets were left without inspection, as in the case of Killian's method; there was also practically no deformity as a result. The first step was to take a radiograph of the frontal sinuses to see their extent, as they were entered from the anterior wall. The first incision was made over the previously shaved eyebrow, the inner end curving slightly downwards to the centre of the root of the nose. The incision should not go through the periosteum. This cut was subsequently prolonged vertically downwards in the middle line to the lower end of the nasal bones. The soft tissues were retracted and the periosteum incised and reflected as much as necessary to gain entrance to the frontal sinus at its inner and anterior aspect. As much as required of the anterior wall and floor of the sinus was then removed. The subsequent prolongation downwards of the incision at its inner end was then made, the knife being here carried right through the periosteum to the bone, and at its lower end was pushed through into the affected side of the nose just external to the septum and made to cut upwards as far as it would go, the remainder being severed with a specially bent saw right into the sinus. A slightly curved incision of about half an inch in length was then made through the tissues down to the bone beneath the lower orbital margin of the same side, its inner end commencing just in front of the anterior lacrymal crest, the lacrymal sac being turned outwards and an opening made here into the nose. By means of a bent probe-pointed saw or a Gigli this opening was connected with the fronto-nasal duct subcutaneously, the nasal process of the superior maxilla was then divided subcutaneously in a similar manner, the bent saw being passed from the opening in the region of the lacrymal sac into the anterior nares. This then freed the osteoplastic flap, consisting of the nasal bone, the nasal process of the frontal and superior maxillary bones, together with that small piece of the frontal which joined the superior maxillary nasal process. The facial artery was left intact. The flap was then turned outwards, and the interior of the nose and the anterior ethmoidal cells brought into view. These latter could be removed, also the posterior cells, and the sphenoidal sinus made visible if necessary. The important point in these further procedures was to keep external to the middle turbinal, a small portion of which should be left as a guide. The flap was then replaced and the operation concluded. A good forehead illumination was essential.

Dr. G. WILLIAM HILL (London) also gave an interesting demonstration, illustrated by photographs and diagrams, copies of which were given to members present, of his method of operating upon the larynx and the application of radium to these parts through a Bruning's tube by direct vision.

Dr. BRYSON DELAVAN (New York) also demonstrated Hay's pharyngoscope for the examination of the posterior nares and larynx. The instrument was based upon the principle of a cystoscope and consisted of a vertical shaft which served as a handle and a horizontal portion which served as a tongue depressor, the distal portion of which contained a small lens and electric lamp, the light being conducted along this to a suitably arranged eye-piece in the manner of the cystoscope. The small lens could be rotated so that any portion of the naso-pharynx or larynx could be examined. It was most useful for cases where the mouth could not be opened or when the patient was lying in bed. Of course, it was of no use for operative purposes. It was made by the Wappler Electric Controller Company, New York.

The Section then joined with the Section of Hygiene and Public Health to discuss

Latent Infections of the Diphtheria Bacillus and Administrative Measures required for dealing with Contacts.

This discussion is reported under the proceedings of the Section of Hygiene.

FRIDAY, JULY 30TH.

Mr. H. LAMBERT LACK (London) read a paper on

The Treatment of Cicatricial Stenosis of the Larynx.

He said at the outset that he would confine his remarks mainly to those cases of cicatricial stenosis of the larynx in children which occurred after diphtheria when tracheotomy had been performed, as in most of them the tracheotomy tube had been inserted in or near the larynx. He considered that diphtheria had no direct connexion with the stenosis, but that it was secondary to the irritation and injury caused by the high tracheotomy. Personally, he had never seen stenosis follow a tracheotomy lower down. The amount of stenosis varied from a slight fibrous thickening to an impermeable stricture. The treatment he adopted was to do a low tracheotomy and to remove the other tube, allowing this wound to close, and, if the original tracheotomy had been performed within a few weeks, the probability was that the laryngeal condition would quickly recover without further treatment. The tube in the trachea should then be blocked for longer and longer periods until the child breathed easily, when it should be blocked night and day. This might take from one to three months. He had previously tried a combination of dilatation of the larynx together with a low tracheotomy, and for this purpose he used T-shaped tubes for the upper opening, but it was found impossible to keep them clean, and he came to the conclusion that the improvement was due to the low tracheotomy, which was the only treatment he now adopted for such cases. Of course, recovery would not occur in cases attended with extensive sloughing or with necrosis of cartilage. He had since tried intubation, but had not obtained any benefit from it. With reference to almost impermeable strictures, he had hitherto regarded them as hopeless and that such patients were condemned to wear a tube all their lives, but he looked forward to the subsequent speakers for help in this direction.

The PRESIDENT remarked that the subject was one of the most interesting that had been brought before the section, and that hitherto its treatment had been one of the most difficult problems of the laryngologist. They had just heard the opinion of one of the foremost British laryngologists, and he was to be followed by Dr. Delavan, who would give them the latest experiences of intubation, which method had been, except in fever hospitals, neglected in Great Britain. Finally, they would have the benefit of hearing the views of Dr. Delsaux, than whom none was more capable of describing tracheo-laryngostomy, and, finally, they would hear Dr. Mayer, of the land of O'Dwyer.

Mr. LACK, in reply, said that he had generally been able to remove the tube in from one to three months. He passed round for inspection one of the plugs which he used in his earlier methods. He had found that an intubation tube introduced from below was more comfortable than one inserted from above; he also gave illustrative cases of treatment in this respect.

Dr. BRYSON DELAVAN (New York) then read a paper on

The Treatment of Cicatricial Stenosis of the Larynx by the Methods of O'Dwyer and Rogers.

He said that, in his opinion, three things were essential in the successful management of these cases—namely, relief of the stricture, permanence of such relief, and as little injury to the parts as possible. He referred to methods previous to O'Dwyer, whose character and attainments he considered worthy of the highest regard. He thought that O'Dwyer's method comprised all the advantages, and none of the disadvantages, of the previous forms of treatment, and this had been shown abundantly by the brilliant series of cases reported by Dr. John Rogers. He referred to certain anatomical factors upon which the principles of intubation were based, and believed that cutting operations would only result in ultimate failure, because of resulting adhesions, even after long-continued dilatation and supposing that cicatrices were also excised. He stated that scar tissue in general when subjected to long-continued stretching would finally lose its resiliency, and it was upon this fact that intubation was based. For this purpose each case should have its own tube specially modified to suit the individual requirements, and the instrument should exert steady and continuous pressure upon the contracted tissues for at least one year. There were various "normal" tubes designed by O'Dwyer from casts to fit average larynges somewhat loosely, and these must be modified to suit the individual larynx, when the acute period had passed away, by passing under general anæsthesia different sizes until one was obtained which the operator considered would effect the desired result without causing sloughing. Then a special tube was made of a suitable length and with a retaining swell, which occupied the space at and below the cricoid cartilage, of the same size as in the trial tube. The neck of this special tube, which pressed upon the hypertrophied intra-laryngeal tissues, should have its transverse diameter $\frac{3}{32}$ inch smaller than the retaining swell or it would be coughed out, while the head, which rested on and in the aryteno-epiglottic folds, must have a diameter $\frac{1}{32}$ inch greater than that of the retaining swell, otherwise the tube would slip into the larynx. These measurements applied to hard rubber tubes, but with metal ones the head should be still a little larger. Occasionally a tracheotomy was essential when there was danger of the tube being coughed out, as occurred at times with hypertrophic laryngitis. Various tubes were here passed round for inspection, including a plugged or clamped tube which consisted of a removeable right-angled piece passing through the tracheotomy wound and screwing into the one already described, which effectually prevented its being coughed out. Tracheotomy should only be performed if absolutely necessary. Vulcanised rubber was an ideal material for a tube, and should first be tried, but occasionally metal was better. He referred to several clinical cases in which recovery required from one month to a few years, two years being perhaps a fair average, and he contended that no other method had yet been tried for a sufficiently long period of time to enable any definite conclusions to be drawn from it. He referred to a temporary spasm of the adductors after removal of the tube which might lead the surgeon to think that the condition was unchanged, but general anæsthesia would determine whether the dyspnœa was due to fibrous stricture or to spasm.

Dr. DELSAUX (Brussels) read a paper on

Tracheo-laryngostomy in the Treatment of Cicatricial Stenosis of the Larynx and Trachea.

He defined it as a large opening of the larynx and superior part of the trachea made permanently or at least for a long period. He excluded cases of tubercle and lupus, and thought that bronchial catarrh was a contra-indication, but considered it possible in all other cases of cicatricial stenosis of the larnygo-tracheal tube. He referred to the care required in preparing for the operation and to disinfection of the mouth and teeth. The operation could be performed under either general or local anæsthesia. The head should be held by an assistant in Rose's position during the whole of the operation. He indicated the instruments required and emphasised the importance of a good frontal mirror. He divided the operation into the following six stages: 1. The preliminary incision extending from the previous tracheotomy wound to the upper margin of the thyroid cartilage. 2. The longitudinal division of the trachea and the cricoid and thyroid cartilages, together with the thyroid isthmus. 3. The suturing of the mucous membrane of the larynx to the skin. 4. Excision of the scar tissue. 5. Introduction of a dilator and cannula, the latter having, of course, an opening at its upper part. The dilator was a rubber tube which should exceed the diameter of the trachea. Fournier introduced his cannula through a hole in the dilator. Some preferred gauze for the dilating material during the first few days, afterwards inserting a rubber tube, so that the patient could learn to breathe again through the natural passages. 6. Dressing of the wound and of the cannula to keep it in position The inner cannula should be frequently cleansed and boiled and the dressings removed as often as necessary. The mouth must be frequently cleansed. The epidermis soon commenced to grow along the granulations which lined the new laryngo-tracheal conduit The dilatation should be continued for a period varying from a few months to a year or longer, and when all the raw area was covered with epidermis the upper part of the wound might be allowed to heal, and later a plastic operation would of course be necessary and should be done at once without any safety opening, when the patient could breathe easily through the nose and was not out of breath when running. The methods that could be used in closing this aperture were next described, either with square flaps of skin or flaps elliptic in shape sutured in the median line with the skin turned inwards. A synopsis of the results of 36 cases was then given.

Dr. EMIL MAYER (New York) read a paper on the

Treatment of Cicatricial Stenosis of the Larynx.

In this paper he instanced three unusual cases in which tracheotomy had been performed. He used intubation and exhibited a special hollow [illegible] ibes could be passed slowly, t[illegible] the handle all the time—one c[illegible] its insertion. The introducer, which was here passed round for inspection, was an excellent one for the purpose. He [illegible] Dr. Rogers [illegible] wan, and [illegible] mportance [illegible] he correct [illegible] uld be no [illegible] first case was due to a bullet which entered the temple, passing downwards through the soft palate into the thyroid gland and then into the œsophagus; it dropped into the patient's stomach and was finally passed per rectum. The second case was due to post-typhoid perichondritis, and the third case was one of granuloma of the larynx, which had been previously operated upon. These were both successfully treated by intubation.

Dr. **HILL** described a laryngeal splint which he had devised for preventing transverse webs and cicatricial bands in the larynx from being reproduced after removal, instancing a case. The patient had satisfactorily worn it for about three weeks. The splint was passed round for inspection.

In the discussion Dr. A. **LOGAN TURNER** (Edinburgh) referred to the difference between the American treatment by intubation and the European by the knife. An objection to the former was the prolonged period necessary in some cases for using the tube. He had had trouble in one of his laryngo-tracheoscopy cases from œsophageal fistula, which had interfered with the maintenance of the lumen of the trachea. In case of post-operative stenosis following laryngofissure he thought that fibrolysin used locally might be of service.

Mr. H. S. **BARWELL** (London) referred to Schrötter's method of intermittent dilatation which had been successful in his hands. One reason why he had avoided intubation was his idea that the tubes required frequent removal and re-insertion.

The **PRESIDENT** said that in his opinion one lesson to be learned from the papers was the sufficiency in certain cases of a low tracheotomy in curing, and better still in preventing, the post-diphtheritic cases. Another lesson was the death knell of Schrötter's tubes, for those of O'Dwyer would do all that Schrötter's tubes could do and even more. Another lesson was the promise held out by laryngo-tracheostomy. He laid stress upon the benefit which the successful treatment of such conditions would confer on society, instancing the case of a little girl whose social life was being sacrificed due to want of laryngeal function.

Dr. **DELAVAN** briefly replied, and showed a concealed knife for the division of cicatricial bands in the anterior commissure. He stated that intubation could not be mastered in a few days, and that he thought it better for one or two specialists in large centres of population to become proficient, so that they might send such cases to them.

Dr. **DELSAUX**, in his reply, said he thought that the epidermis took up the character of mucous membrane. He had had no good results from fibrolysin. To prevent any secondary stenosis a piece of cartilage might be inserted prior to performing the plastic operation.

Dr. R. H. **SCANES SPICER** (London) read a paper upon the

Relationship of Cancer of the Throat to Abdominal and Thoracic Breathing,

which depended, amongst other things, upon posture and distension of abdomen. He illustrated his remarks upon a model made for the purpose.

Dr. R. H. **WOODS** (Dublin) showed a patient whose larynx he had extirpated, and exhibited a method which he had adopted for enabling the patient to speak. For this purpose a reed was introduced into the distal end of a tube which was carried from the tracheal opening through the nose into the pharynx, by this means reinforcing the resonance of that cavity for vowel sounds.

A short paper by Dr. J. **HARDIE NEIL** (New Zealand) was read by Mr. G. A. **BARTON** (London), on the

Surgical Anatomy of the Tonsils,

in which the author differed from Dr. D. R. Paterson as to the downward extent and relationships of the supra-tonsillar fossa.

A vote of thanks to the President concluded the work of the section.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 28TH.

President, Fleet-Surgeon J. LLOYD THOMAS, R.N.

The **PRESIDENT** delivered an address of welcome to the members of this section.

Colonel H. E. R. **JAMES**, R.A.M.C., communicated a paper entitled

"An Account of the Officers' Training Corps, with Special Reference to its Medical Branch."

He said that for reasons of expediency it was obviously unnecessary to maintain the medical establishment of the army at war strength during times of peace, and upon the outbreak of war upon a large scale a call would be made upon the civil medical profession for the completion of the medical establishment of the expeditionary force. About 50 per cent of its medical complement would consist of medical men not of the regular army medical service, and the existing reserve was totally inadequate to provide this number. A "special reserve of officers" was designed to meet the case, but under the most favourable conditions it was unlikely to produce the large body of officers required, as many men were loth to bind themselves to undertake war service in prospective, while it was also obvious that a man knowing nothing of the medical service must be at a great disadvantage under conditions of field service. Therefore the giving of a free hand to schools and universities without binding the recipients to service was a measure which promised well, even if it should not fill the special reserve and the Territorial Force as was hoped. That was the origin of the officers' training corps. The general object of the organisation was to provide officers for the regular army, for the special reserve of officers, and for the Territorial Force, and its method of working was to give a standardised measure of military training to boys and young men of the educated classes at schools and universities. The university contingents formed the senior and the school contingents the junior division of the officers' training corps. No physical examination was imposed, the only regulation being that the cadet shall be able to perform his duties to the satisfaction of his commanding officer.

Lieutenant-Colonel R. **PORTER**, R.A.M.C., read a paper on

Physical Training of Recruits in the Army.

He said that the object of physical training should be to increase intelligence, quickness of movement, power of endurance, and keenness for work; in other words, physical training meant the gradual training of the heart and lungs to accommodate themselves to the demands of muscular exertion, and the undertaking of fatiguing exercises without undue distress. The recruit on joining the army at the age of 18 years was not physically fit to undertake the duties of a soldier without considerable preparation, and it was by this system of physical training that he was prepared for the strenuous and active life which was now required of a soldier. In carrying out these exercises his body was gradually and harmoniously developed, faulty postures were corrected, and at the end of his training his standard of physical fitness was enormously increased. All this was done without any undue strain to the body, and in practice it was found that generally recruits after three or four months' training improved in weight, chest capacity, and the harmonious working of heart and lungs was well seen in their power of running one mile without distress, as shown by their respiration and pulse-rate. The methods by which this training was carried out were based on the Swedish system, which had been introduced into the British army within the last few years, and differed entirely from any system of physical training previously employed in England. The methods in vogue in the army a few years ago, and indeed in the universities and schools, were very unscientific and opposed to all physiological laws. They tended to produce a state of abnormal muscular development. What was aimed at now was the harmonious development of the whole body without strain to muscular, respiratory, or circulatory systems. Great care was taken to avoid hurry in physical training. It was impossible to obtain good results by cramming more work into the same or less time. The object aimed at in these physical exercises, particularly of the arms and legs, was not exactly the development of the different muscles engaged, but their increased efficiency and power of resisting fatigue. Generally speaking, in all recruits the trunk muscles required development to correct faulty postures acquired in civil life. Stability was necessary if work was to be performed efficiently and economically, therefore the muscles which maintained stability must be systematically developed. Over-distension of the chest was injurious, as it was liable to diminish the elasticity of the lungs and render them less efficient. But exercise performed with a good carriage of the spinal column and directed towards securing the coördinate working of the heart and lungs was in the highest degree beneficial. The judicious and progressive employment of marching, running, jumping, and kindred exercises was the best means of obtaining true coördination. The usual time occupied in training recruits so as to prepare them for the active work of a soldier was six months—namely, three months at the regimental depôt and three months after joining their respective battalions. During this time they were constantly kept under medical supervision, and if it was seen that at any time the work was too severe or likely to produce strain in any individual he was put back to a class where the exercises were more simple and work less severe.

This paper was discussed by Colonel T. H. Hendley, I.M.S. (retired), Staff-Surgeon E. Cox, R.N., and the President, after which Lieutenant-Colonel Porter made a brief reply.

Colonel T. H. Hendley, C.I.E., V.D., I.M.S. (retired), read a paper entitled

"*A Contrast between the Treatment of the Wounded under the Mogul Emperors and King Edward the Seventh, Emperor of India.*"

He said that in the time of the Mogul Emperors surgery was left to quacks or barbers, and in India to jarahs, who were combinations of both. They used salves, or plunged stumps into boiling oil, especially after gunshot wounds, which were regarded in India, as in Europe, as being poisoned. The real difference between the old and new conditions in India was that in the past there was no system; in the present the State had made itself responsible, though it must be assisted by individual effort. The main principles of the present methods were—to follow up the fighting line so that the wounded might be succoured as soon as possible after they fell; their speedy, and, as far as might be, comfortable, removal to a place of comparative safety, and then to some place at which they could be properly treated in view of returning them when fit at the earliest date to the front. When the casualties were few and not widely spread relief could usually be quickly afforded by trained persons; but if a man fell at a distance from such skilled assistance and the battle was a great one, it would be impossible to attend to all who fell even for some hours. In such cases the only hope for the individual was that his comrades or even he himself might be able to afford what was so appropriately termed "first aid." Briefly, this was to stop hæmorrhage, to apply first dressings to wounds, to put broken limbs into a position of safety, to relieve thirst, and to assuage pain by the use of sedatives, and then to arrange as soon as possible for removal from the danger zone. He desired to urge with special force the regulations which provided that every soldier should be taught so much. His own life and the lives of his comrades might depend upon his possessing such knowledge. If the "first aid" was properly understood and rendered, the experience of modern war, and especially of the Japanese war, showed the chances of recovery were enormously enhanced, and further that satisfactory "first-aid" treatment was usually sufficient to make a soldier safe until he could be transported to base hospitals, even if they were at several days' distance. So important was this training that there should be no shirking it, for every man who had not acquired it was a danger to others and a source of weakness to the army.

Lieutenant-Colonel Porter said that the Royal Army Medical Corps was now well organised, and he thought that in future this work should be left in the hands of the field ambulance.

Lieutenant-Colonel E. M. Wilson, R.A.M.C., thought that possibly there might be a tendency to teach the rank and file of the army more than was absolutely necessary in first aid and ambulance duties. He thought that it would be best to limit the training to first aid only and the application of the first field dressing, which every soldier carried.

Colonel Hendley, in reply, said that soldiers should have some knowledge of first aid, and it was not intended that they should take the place of the Royal Army Medical Corps.

Thursday, July 29th.

Fleet-Surgeon P. W. Bassett-Smith, R.N., communicated a paper on

The Diagnosis of Syphilis by some Laboratory Methods.

He first considered the microscopic demonstration of the *Treponema pallidum*, which he had not found to be of much practical use on account of the labour which it involved, although when successful he considered it diagnostic of syphilis. Turning to the macroscopic method he described the technique adopted in performing Wassermann's serum test, and some of its modifications, and concluded with the following summary of the results obtained by it. He found that almost all cases with evident primary syphilis gave a marked reaction to Wassermann's test slightly modified, using for antigen dried congenital syphilitic liver. This reaction was obtained as early as the fourteenth day after infection; in many cases admitted for chancroids the presence of a double infection was early indicated by the test; in almost all cases of early secondary syphilis with or without symptoms at the time, positive results were obtained; in late secondary stages or tertiary manifestations the results were more variable; in about 50 per cent. of parasyphilitic cases a positive reaction was present. In cases without symptoms and generally after much treatment, but with an undoubted history, a minority reacted. The reaction was specific for syphilis as far as other venereal diseases were concerned. Mercurial treatment did not appear to prevent the reaction when symptoms were present. By this method they had a valuable aid in the diagnosis of syphilis, deciding the nature of many difficult cases and early indicating the need of specific treatment.

Colonel F. J. Lambkin, R.A.M.C., read the following paper on

The Arylarsonate Treatment of Syphilis: its Probable Future Effects in the Services.

He said: In discussing the question of the treatment of syphilis by means of arylarsonates it is no intention of mine to compare it with that by mercury. The position of the latter is perhaps stronger now than it has ever been, for after having gone through various vicissitudes in the ups and downs of heated discussions, it has, especially during late years, been generally accepted as *the* specific for syphilis; nevertheless, there were, and are, cases which resist mercury in any form, cases to which mercury cannot be given owing to their extreme susceptibility to it, and for such the necessity of finding a substitute was all-important. At our last annual meeting at Sheffield I had the honour of reading a paper on the treatment of syphilis by arylarsonate salts, recording up to that date 54 cases so dealt with and with favourable results,[1] and it is my intention now to bring further evidence to prove the utility of these salts in the treatment of the disease. Since August, 1907, when I first began to use the arsenical compound, my colleagues and myself have treated over 130 cases with it. In these cases syphilis was represented in all forms and stages, from the typical Hunterian chancre accompanied by enlargement and hardening of the inguinal and cervical glands to cases showing the different forms of syphilitic rashes, as also others in the later stages with various forms of syphilitic lesions, including signs of commencing tabes. Most of these did remarkably well. In the cases of Hunterian chancre this soon softened and passed away, the majority showing no signs of return, and in many there were no further developments of the disease. Syphilitic rashes rapidly disappeared, ulcers of the mouth and throat healed, whilst the gain of body weight was most marked from the beginning; at the same time anæmia and cachexia cleared away. The most interesting effects of the treatment were seen in cases in the later stages of the disease, of which the following are a few:—

First case.—A. B., aged 45 years. The disease was contracted 24 years ago when he had a chancre followed by a roseolar rash and sore-throat, and later a profuse papular pustular eruption broke out over the body. He received what appeared to have been a very complete mercurial treatment by the internal method and chiefly by means of hydrargyrum cum creta. He had spent many years in the tropics; said that he was obliged to take the specific almost continuously, otherwise the disease was certain to break out in one form or the other; this had been the case for years past. When I saw the patient he was much debilitated and anæmic, suffered from periodic nocturnal

---

[1] See The Lancet, Sept 12th, 1908, p. 809. A further paper by Colonel Lambkin describing 21 cases of syphilis successfully treated with arylarsonates was published in The Lancet of Dec. 5th, 1908, p. 1656

Fourth case.—G. H., aged 34 years. He contracted syphilis in India eight years ago, having a chancre on the penis, followed by a roseolar rash and sore throat. He went under *specific treatment at once*

cum creta. Since then he had had very many fresh outbreaks of the disease constantly, mostly of sore throats with mucous patches on the

These are a few of the most interesting cases treated by the arylarsonate salts. They are peculiarly interesting from the fact that hitherto their utility was doubtful as regards syphilis in its later stages. In forming an estimate as to how far these compounds are capable of preventing further ravages of syphilis it would be necessary to watch the progress of a number of cases which had been treated solely by them, which is a matter of very great difficulty, even in the army and navy, where men are continually being lost sight of owing to taking their discharge or to being transferred elsewhere. Among the cases treated I only saw slight toxic symptoms in two, and this was in the case of two patients both over 55 years of age. The symptoms consisted in one patient of slight colic with nausea and vomiting, in the other of browache and dizziness. All the other patients underwent full courses without interruption.

Preparation used.—The preparations of arylarsonates which were used were as follows: (1) atoxyl (arsonate of sodium); (2) soamin (amino-phenyl-arsonate); (3) arsacetin; and (4) arseno-phenyl-glycin (in vacuo). The first of these—i.e., atoxyl—was the original compound of arsenic which was tried for sleeping sickness and later for syphilis. With it I *treated some 24 cases of the latter* and with much success; no untoward symptoms occurred. Nevertheless, I was obliged to abandon it owing to the ill reports which came in concerning the danger of its use, as also after having seen four cases of total blindness which followed its use for sleeping sickness in Uganda. The second preparation, soamin, was introduced by Messrs. Burroughs and Wellcome of London. It is a sodium amino-phenyl-arsonate and almost identical with the old preparation atoxyl, except that being of a definite chemical composition and arsenical strength (which atoxyl is not), it can be administered with much greater safety and confidence than a compound liable to variation in strength as is the case with atoxyl; in other words, it is a stable preparation. Soamin has been used very extensively at the Military Hospital, Rochester-row, and with very great success, and with the exception of the two cases above mentioned none of them were followed by toxic signs. The salt is made up in solution for use and is given either subcutaneously or intramuscularly; on account of its tendency to decomposition from keeping the solution needs to be made up afresh at least daily. The dose which I have been giving is 10 grs. every second day until a total of 100 grs. has been attained. The third preparation used—i.e., "arsacetin"—was introduced by Ehrlich as an improvement on the original atoxyl.[2] He *describes it as the acetyl derivative from the latter and for* short called it "arsacetin." Of it Neisser remarks: "1. Arsacetin is certainly far less toxic than the old atoxyl, both healthy and diseased animals tolerating much larger doses of it than of the latter. 2. Its remedial action on syphilis was at least equal to the older preparation. [In my judgment this is quite borne out by my practical experience.] 3. *No decomposition of any kind in the solutions,* even when stored for a long time, could be detected; even boiling daily did not alter the solutions in any way." This preparation I use in 10 per cent. and 15 per cent. solutions. The latter has the advantage of not requiring so large a quantity of fluid for injection, consequently causing less pain than the weaker solution; on the other hand, it has the disadvantage that it deposits the salt when cold and requires to be reheated before being used, so as to bring the latter into solution again.

Dose.—I have been giving 50 minims of the 15 per cent. solution which represents 8 grains at each injection every alternate day until 100 grains have been totalled. Whether it is better to give *injections on two consecutive days, or* whether more favourable results would be obtained if they were given less often but in larger doses, has yet to be decided, but judging from the analogy of experience in
favour the former.
sacetin very extensively
, and not one case has
shown any toxic symptom. I found that in the majority of cases it promptly removed symptoms and the patient's general condition was much improved, whilst in others it failed, and recurrences took place during and immediately after a course of it; on the other hand, it very often succeeded where mercury had failed. Its beneficial effects were most apparent in the older cases (late stages), some of which responded to it in a wonderful manner. The great disadvantage of atoxyl is that it is not stable as regards strength, also owing to the liability of its solutions to decompose, thereby forming dangerous by-products, and it cannot be denied that if the risk of optic atrophy has always to be run even after a moderate dose one would hesitate before employing atoxyl. Soamin is far preferable to atoxyl, although it is practically the same salt, the fact being that it is of stable strength and consequently its toxic effects are very limited always, provided that certain points, such as using only freshly prepared solutions of it, are adhered to and always remembering

---

[2] THE LANCET, Dec. 5th, 1908, p. 1682.

the liability of its solution to decompose on being stored for any time, and that they cannot be sterilised owing to chemical changes taking place on boiling. Arsacetin, besides being less toxic than either atoxyl or soamin, has the great advantage that solutions of it do not decompose on being stored or boiled, hence it is practically free from the dangers of the latter salts. Of the newest preparation—i.e., arseno-phenyl-glycin—sufficient time has not elapsed to allow of anything like a definite opinion being given; at the same time the fact of its requiring to be supplied in vacuo and the danger attached to it on its exposure to air appears to me to put it out of count for anything like general use, more especially as the little glass tubes in which it is supplied are very apt to get cracked in transit, thus exposing the salt to the air. For the present I think that the advantages are decided on the side of arsacetin. As already stated, it has been used a great deal by myself and with no untoward effects. As a rule I have employed it alone, whilst in other cases I have made use of it in combination with mercury, giving both simultaneously with very good results. With more extended experience the advantage of employing mercury and arylarsonates together in certain cases of syphilis is becoming daily more impressed on me. One thing is certain—i.e., that many cases of syphilis which responded readily to one of those agents may be totally unaffected by the other and *vice versâ*, and this without any reference to their susceptibility to either, which leads me to the conviction that there are different strains of spirochæta pallida which are affected differently by mercury and arsenic. The presence at the same time of these different strains in the same individual may explain the good which follows the employment of mercury and an arylarsonate. On the other hand, there might be an advantage in giving them both alternately. Perhaps there might be an advantage if arsacetin and mercury were employed alternately.

Contra-indication to arylarsonates.—For the present it is at least advisable to proceed cautiously with the employment of arylarsonates and to do so in those cases where no parenchymatous organic changes are observable, as it appears that already diseased or enfeebled organs are more susceptible to their toxic action, hence cases showing signs of cardiac or renal organic disease should not be submitted to treatment by these salts.

How the treatment should be proceeded with.—The question as to how to proceed with the arylarsonate treatment—i.e., as to when a second or third course should be commenced—has naturally been the subject of much thought as it could only be decided by careful observation and clinical experience. The plan in vogue at present at Rochester Row is to repeat the course in three months' time in all cases after the cessation of the first (earlier in cases showing a recurrence of symptoms), and a third course is given in six months' time in all cases, whether showing signs of the disease or not.

The arylarsonate treatment as a prophylactic.—At the meeting of the Medical Congress at Berlin, 1907, Metchnikoff made the statement that by injections of atoxyl he had succeeded in preventing further developments of syphilis in cases of undoubted syphilitic chancre and strongly advocated it as a prophylactic; the number of injections which he succeeded with was three of 10 grains each. His statement was very thoroughly tested in our army—i.e., at certain of the largest military stations every second case of venereal sore of whatever description which was admitted into hospital received four injections of 10 grains of either atoxyl or soamin and a careful record kept. The experiment showed that the injections did not prevent further developments of the disease in any way, so that from a prophylactic point of view their use must be considered a failure.

As a curative measure.—In considering the question as to the value of these arsenical compounds, either from a preventive or curative point of view, I would remark that to judge the efficacy of a syphilitic remedy from its symptomatic relieving action is wholly false, considering the proof which has been furnished by experiments on animals that these salts possess a reliable curative virus-destroying action. It is therefore our duty to utilise this experience gained with animals in the treatment of syphilis, although in the human subject we may at present not be able to produce proof that these arsenical salts are capable of eradicating the disease and can but observe their [illegible] symptoms; still, there being no [illegible] power, we ought to make the most of this possibility. There is no necessity to confine ourselves exclusively to the use of mercury or these arylarsonates, as both will be equally useful in certain cases, either alone or when employed [illegible]

What effect the introduction [illegible] treatment of syphilis will have in the services it is impossible to foretell, but that they are destined to supersede mercury is most unlikely; on the contrary, I believe that their introduction will strengthen more than ever the position of the latter, as by its combination with arylarsonates it will be feasible now to deal successfully with those cases which had hitherto for some reason or another resisted it when administered alone. There is a class of case to which these arsenical compounds ought to be a veritable boon—i.e., those to which it is impossible to give mercury in any form, owing in some cases to an idiosyncrasy, in others to the patient being debilitated and broken down from climate or other tropical influences, and especially to those cases of syphilis which are deeply tainted with malaria. On the whole, I believe that the introduction of the arylarsonates in the treatment of syphilis will have an important influence in the services, as they will undoubtedly tend to lessen the admission rate as also that for invaliding. Our present knowledge of the power of these salts of arsenic over syphilis is only in a very elementary stage, but I look forward to further experience of them and improved technique leading us to that goal in the treatment of syphilis which has already been attained with dourine.

A short letter was read from Major H. C. FRENCH, R.A.M.C., in which he said that the test of benefit in early syphilis was the rapid reduction of induration in the chancre and in the lymphatic glands. He had not found soamin or arsacetin nearly so valuable for that purpose as mercurial inunction with baths.

Major G. S. CRAWFORD, R.A.M.C., communicated a paper on

The Beneficial Results of Recent Sanitary Work in Malta.

He said that if they could prove that by sanitary measures they were able greatly to reduce the number of sick they would secure the active coöperation of all ranks in the army. In Malta they had proved that beyond any shadow of doubt. There were many great advantages in keeping the army healthy. It gave the regimental officers a much better chance of efficiently training their men and fitting them for active service. It was a great saving to the State and it helped recruiting, for the reason that nothing tended more to deter men from joining the army than the state of many invalided soldiers. The paper went on to deal with Malta fever, enteric fever, tuberculous disease, pyrexia of uncertain origin, dysentery, rheumatism, and infantile enteritis.

A discussion followed in which Inspector-General R BENTHAM, R.N., and Colonel HENDLEY took part.

Colonel P. BROOME GILES, A.M.S. (A.M.O, 1st London Division Territorial Force), read a paper entitled

"*On the Importance of the Permanent Attachment of Ample Transport under the Command of the Medical Officer of each Field Medical Unit.*"

He said that the history of war in the past and the experience of peace manœuvres not only proved but emphasised the failure of detailed transport for the use of medical units If the transport was detailed on requisition from the Army Service Corps considerable delay was often inevitable, and even in cases of emergency hours often elapsed before the transport demanded was supplied. Whatever might be said to the contrary, there was no escaping the fact that there was a very possible element of discord in respect to discipline; the detailed *personnel* of one branch of the service could not have the same intuitive feeling of obedience to officers of another branch that they had to their own, and with hired civilian transport there was greater trouble, as civilians were strangers to discipline, generally unpunctual, and accustomed to their regular hours at their own pace. The horses generally were unfit for the work, being untrained and unaccustomed to service environment, and the harness faulty. It was a most elusive thing to think civilian wagons and harness would do for medical units, and he could not imagine anyone with practical experience advocating such procedure. The advantages of permanent transport were that the transport sections recruited for each medical unit were homogeneous, part and parcel of the permanent *personnel*, and practically of the same social rank from which the unit was chiefly recruited. In Territorial medical units hired civilian transport could never be popular or successful. Under the present conditions men had enlisted to the transport sections keen for work, but when they realised that their practical training would be with civilian wagons and harness their enthusiasm would dwindle away. If something was not done he feared the good men would languish and their places would be taken by those who refused the yeomanry, and wanting to wear spurs would join the transport section for that inducement. They should approach the subject from two practical sides—that permanent transport was requisite for each field ambulance, and that to obtain the highest efficiency it must be part of the *personnel*, and its *matériel* must be that of the regular force. The more the Territorial unit coordinated with its Regular branch the higher the efficiency and discipline.

The PRESIDENT pointed out that though permanent transport was to be preferred nevertheless circumstances occurred which demanded the use of civil appliances.

FRIDAY, JULY 30TH.

An interesting paper was communicated by Staff-Surgeon F. F. MAHON, R.N., on his experiences when serving in H.M.S. *Minerva* off Messina, when that town was destroyed by earthquake.

Mr. J. M. CARVELL (London) read a paper on

The Existing Ambulance Organisation of the Home Railway Companies, with Suggestions for its Amplification and Unification.

He said that the course of instruction which railway ambulance men went through was in accordance with the syllabus of the St. John Ambulance Association. It extended over a period of five weeks. There were five lectures with an interval of seven days between each, followed by an examination. The examination consisted of a practical and a theoretical portion. Encouragement to take up ambulance work was given in different ways on different lines, such as rewards for proficiency, rewards for work done, additional passes, medals, certificates of honour, competitions, and prizes. The great incentive to railway ambulance work was the inter-railway shield, which was offered for annual competition by the St. John Ambulance Association. Each railway had the right to send a team of five men to compete As to amplification, he considered that all railway ambulance men should be given an elementary knowledge of nursing and sanitation. The men's wives should also be encouraged to go through elementary instruction in home nursing and sick room cookery. In regard to transport, all guards' vans should be suitably fitted for emergency ambulance work. In his opinion the easiest method of unification would be through the St. John Ambulance Association. All railway companies which had not already done so should form centres of the association and a home railway committee should be formed. The members of the committee should be nominated by the railway companies and by the St. John Ambulance Association.

Captain W. SALISBURY-SHARPE, R.A M.C., T.F., said that the result of prize competitions was too often to develop a few teams of highly skilled men rather than a large number of competent ones, the latter being the result to aim at.

Lieutenant-Colonel E. M WILSON agreed with this remark, but he was of opinion that probably better results would ensue from consultation between those responsible for teaching in the different railways than by asking the authorities concerned to lay down additional rules and regulations.

Colonel HENDLEY considered that it would be best if the railways could consult amongst themselves in the hope that they might arrive at greater uniformity and that the benefits of training might be more widely extended, for he thought with other speakers that improvement was needed, as there was a strong tendency for a few enthusiastic men to acquire skill and for the great body of railway servants to be discouraged and not to keep up their knowledge.

Mr. W. C RIVERS (Newcastle-on-Tyne) read a paper on Rhinology as an Aid to Diagnosis of Pulmonary Tuberculosis, with Special Reference to the Physically Selected Classes. and the work of the section was concluded with the reading of a paper by Staff-Surgeon J. G. WALLIS, R.N., describing a Detailed Scheme for an Unexpected Landing Party using Material Available on Board Ship.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 20th, 1831.

HIS MAJESTY has been graciously pleased to confer the honour of knighthood on Richard Dobson, Esq., chief surgeon of Greenwich Hospital, for his long and distinguished services, with permission also to wear the orders of St. Wladimir, of Russia, and Danebrog of Denmark, which the late emperor Alexander and the King of Denmark transmitted him through their ambassadors, for eminent professional assistance rendered to their respective subjects whilst in the hospital ship at Chatham. From this circumstance we are inclined to believe, that the recent movement in behalf of naval surgeons, has not been without its effect in a certain influential quarter. Hitherto the favours of royalty have been almost exclusively bestowed on surgeons of the army.[1]

HARVEY'S TREATMENT OF GOUT.—Harvey was a great martyr to the gout, and his method of treating himself was singular. He would sit with his legs bare, even if it were frosty weather, on the leads of Cockaine House, where he lived for some time with his brother Eliab, or put them into a pail of water, till he was almost dead with cold, and then he would betake himself to the stove; and so it was done.

Sept. 1st, 1847.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. A. A. H. D. Ilin has [illegible] Professor of Medical Chemistry.

THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1909.

The Reorganisation of the International Congresses of Medicine.

WE are informed that some effort may be made at the forthcoming International Medical Congress at Budapest to modify and improve the organisation of future congresses, and presumably the attempt at reform will be directed towards international congresses dealing with the other sciences allied to medicine, such as congresses for the study of preventive medicine or hygiene. The International Association of the Medical Press, which meets at Budapest during the two days preceding the International Medical Congress, will discuss a project prepared by the British section of this association which has considerable interest in this connexion. This is a draft of a constitution to govern the selection of the International Committee, which is the supreme authority over these congresses, to extend the powers of this committee, and also to create a smaller executive committee, meeting at least once a year and employing a permanent international secretary. With a definite supervising authority, an active and experienced executive, and a general secretary well versed in the three languages of English, French, and German, well paid, and devoting his time to the work, it is thought that something like order might be evolved out of the present position, which we only hesitate to call chaos lest we should be misunderstood as belittling the great efforts of past general secretaries. The congresses should be so circumscribed as to become manageable. It is universally recognised that congresses consisting of many thousand members are too unwieldy for practical purposes. They also occasion enormous expense, and as their results do not seem to justify their cost there is a possibility at any time of a projected meeting failing to secure a home and an adequate subsidy. Probably it is not only necessary to reduce the number of members but to exercise more supervision over the communications so as to prevent the reading of commonplace and stale papers which lead to vast waste of time. No one has a more practical knowledge of all the defects of congresses than the members of the medical press who have travelled from town to town, attending congress after congress, and have been compelled on each occasion to obtain an accurate idea of what has been done, so as to record what is the net result of such a multiplicity of effort. Therefore it is only natural that a project of reform should emanate from the International Association of the Medical Press.

Judging from the experience which we have acquired at THE LANCET from the chronicle of many congresses, it may be said that the earlier congresses of hygiene were the best organised of such gatherings that have yet taken place, while these congresses have always been better organised than the medical congresses. This is perhaps as would be anticipated, for the proceedings at congresses of hygiene have a more practical and direct bearing on the legislature of different States. A much larger proportion of the questions to be discussed are fit subjects for, and are ultimately translated into, Acts of Parliament. Many subjects brought forward at medical congresses are at first studied as matters of pure science; they become the base of future laws, but the connexion between the points discussed and the legislative clauses that ensue is neither so frequent nor so direct. A congress of hygiene having definite legal measures as its objective tends to be definite in the scope of its recommendations. Again, in regard to organisation of congresses, it is part of the education of many of the attendants at a congress of hygiene to understand what is meant by organisation. As members of public administrative bodies they know the value of the concrete as against the vague proposal; as engineers or as architects they have to deal at first hand with trade problems which force their views upon the notice of governments. The medical men who naturally attend congresses of hygiene are many of them medical officers of health who have acquired administrative experience and capacity. All this is different with the vast majority of the medical men who attend international medical congresses and whose lives are devoted to the treatment of the sick and the study of medical or surgical therapy. It is excusable that attendants at purely medical congresses should be less able to appreciate the benefits of being organised. But the confusion may become serious when a medical man who is appointed to some important post in the organisation of a congress, not because he is a good organiser but because he holds a prominent position in the medical profession, finds that he has not the necessary qualities for his post. Yet how often a very distinguished physician or surgeon is elected to preside over a general meeting or a section when he has no experience whatsoever of conducting a debate, does not know the form of putting resolutions, amendments, and riders, and fails consequently to control an assembly, whose proceedings accordingly drift into disorder, and whose recommendations are lost to the common stock of wisdom of the congress. By all means let there be as many *Présidents d'Honneur* as may prove agreeable to those concerned, but when there is practical work to be done it should be entrusted to those who are accustomed to that particular sort of work.

When a really important gathering takes place at which many persons are present we inquire immediately what was the upshot of it all, what was done, what was decided. These are questions to which the present manner of procedure affords no chance of ready answer. When a congress consists of three to four thousand members, and that we learn to be the estimated size of the Sixteenth International Medical Congress, and when this crowd is divided up into 20 or more sections, it is not possible to get the members together to decide upon any really debatable question. At the earlier congresses of hygiene at Paris in 1879, at Geneva in 1882, and at The Hague in 1884, there were only a few hundred members. In the mornings there were meetings of sections, at which all sorts of subjects germane to the purposes of the congress were debated. In the afternoons the entire congress assembled; one or two subjects that were thoroughly ripe for discussion were introduced by the best-known authorities present, were intimately explained from different points of view and discussed up and down, and then a vote was taken which, being recorded by the entire congress after an enlightening debate, exercised (and deserved to exercise) great influence on various legislatures. But this did not preclude the presentation to the entire congress of other more purely scientific questions on which no vote was needed or taken. Thus PASTEUR, it may be remembered, reserved for the International Congress of Hygiene that met at Geneva in 1882 his first public communication on the attenuation of the virus of rabies. When his pupil, Dr. ROUX, at Budapest in 1894, had a similar communication to make on the antitoxin for diphtheria this could not be delivered before the whole congress. There were now 3000 members of the congress and no place was available big enough to hold them, therefore Dr. ROUX had to read his paper in the Bacteriological Section, which was overcrowded, while other sections were so deserted that some of them adjourned. With the numerous attendances which spread of scientific education and growth of facilities for travel now bring about it is only possible for all the members of an international congress to meet for the mere formal opening and closing. No debate is possible in such circumstances, and the resolutions that have been carried in the sections are simply confirmed by the entire congress out of politeness and because everyone is on the point of departure and would miss their trains if any discussion was attempted. If there are to be only speeches and lectures it does not matter how many persons attend a congress, but if the recommendations of the congress as a whole are to receive attention the numbers must go down. Article IX. of the regulations of the Sixteenth International Congress of Medicine says that the International Committee will meet on the third day of the Congress to select the town where the ensuing Congress is to be held. This will be a good occasion for discussing how the Seventeenth Congress shall be organised. The committee, say the regulations, will consist of "the presidents and secretaries of the national committees, the president and general secretary of the Sixteenth Congress." They will have a delicate and difficult task before them if they attempt to reform the organisation of the congresses. But this is so much needed that it is to be hoped the committee will not shrink from the task, for the longer the necessary reform is postponed the more embarrassing will the work become.

◆

The Treatment of Sarcoma by Bacterial Toxins.

A MEETING of the Surgical Section of the Royal Society of Medicine was held on July 13th, for the purpose of hearing an address delivered by Dr. W. B. COLEY on the Treatment of Sarcomatous Growths by the Injection of Toxins Prepared from Bacteria.[1] The matter is certainly of sufficient importance to justify our devoting attention to the process he employs and to the consideration of the results which his treatment has produced. Remedies for cancer have never been lacking. They arise from all parts of the world, and their introduction is generally heralded and accompanied by fulsome eulogiums of the wonderful results which they can produce. Yet, whatever may be the cause, the reputation of every one of them is short-lived. Mr. H. T. BUTLIN, at the debate which followed upon the delivery of Dr. COLEY'S address, said that during his professional life he had seen or heard of very many cures for malignant disease, and he had found that they resembled one another very closely in this respect—that they had all passed through an identical series of stages. At the beginning of the career of each cure the treatment was said to remove with certainty all forms of malignant disease. But a few weeks or months at most disposed of this claim, and then the second stage followed, in which the treatment was put forward, not as a universal cancer cure, but as capable of curing certain forms of malignant growth. Later still the third stage came, in which, though the powerlessness of the treatment to cure completely any form of cancer was given up, it was urged at least that it modified the rate of growth of the cancer and rendered it more amenable to other methods of treatment. But the last stage was never long delayed, and that was oblivion. There is much truth in this witty summary of the career of cancer cures; those which have appeared within the memory of the living have conformed to this pattern, and the records of medicine show that past centuries were equally prolific in cures of transient reputation. All this unhappy experience must go far to dishearten those who are most interested in the cure of malignant disease. So many attempts have been proved to be utter failures that the idea naturally arises, "Shall we ever attain to a cure of this affection?" And we are led to regard with suspicion any drug or treatment which is claimed to cure malignant growths. Such a mental attitude is only natural, for our expectation of the future must rest mainly on our knowledge of the past. But this attitude is wrong, for our knowledge of what has been done by medicine should make us hopeful of what medicine can do. We would not for a moment urge that every method of treating cancer which is put forward should be received at the estimation of its introducer, but we would urge that every method the claims of which are supported by any tangible evidence is certainly deserving of a reasonable trial.

The difficulties of examination of the evidence in favour of a cancer cure are great In the first place, doubt as to the diagnosis is very difficult to overcome. Every growth is not a cancer, though to the unlearned mind it is sufficient for a tumour to be large or painful for it to be regarded as cancerous in nature. But even members of the medical profession may be mistaken in the diagnosis of malignant disease. Time and again it has happened that mistakes have been made on this point, and therefore before we can acknowledge that the growth which has disappeared by any treatment was cancerous in nature we must have more evidence than the mere presence of the symptoms and signs usually accompanying a malignant growth. The most satisfactory of all forms of evidence is histological examination, but here again those who have had the most experience of the histological examination of pathological tissues will be the first to acknowledge the difficulties that sometimes occur in the diagnosis. Especially is it difficult to distinguish between a small round-celled sarcoma and granulation tissue, though similar difficulties occur also in other forms of malignant growth. Many a time a hard mass in the neighbourhood of the pylorus has been diagnosed as cancerous and has been removed, yet when submitted to histological examination it has not been found possible to say with certainty that the mass was carcinomatous in nature. In other cases a similar mass has been exposed by a laparotomy, and the clinical signs were so definite and the mass so fixed that the surgeon considered the growth to be incapable of removal, and therefore he has closed the abdomen; but the subsequent course of the case to recovery has shown that the diagnosis itself was erroneous. It is thus seen how very difficult it is to establish beyond doubt the malignant nature of many growths, but the most satisfactory proof that a growth is malignant is afforded in the case of a recurrence of a growth, when the primary tumour has been shown unequivocably to be malignant by histological examination.

---

[1] THE LANCET, July 17th, p. 173.

The basis on which Dr. COLEY has built his theory and practice for the treatment of some forms of malignant disease is probably well known to most of our readers. It has from time to time been recorded that a malignant growth, in some cases carcinomatous, in others sarcomatous, has lasted for a longer or shorter time, and has steadily progressed, so that its course suggested a certain fatal issue before long. Yet an intercurrent attack of erysipelas has been followed by a complete disappearance of the original tumour. Accordingly it has been claimed that the attack of erysipelas caused the growth to disappear. It must be acknowledged that in a large proportion of the cases in which such an occurrence has taken place the diagnosis of malignancy was mainly or entirely clinical and not based upon evidence which would have satisfied the more rigorous criteria of modern medicine. For most of these cases date from more than 30 years ago, when our diagnostic methods were less exact than at the present time. On the other hand, we have to bear in mind that the comparative rarity of erysipelas in hospitals at the present day diminishes greatly the chance of such a disappearance of a malignant growth. Nevertheless, in spite of this objection, we are justified in accepting the records of the clinical facts that malignant growths have been observed occasionally to disappear during an intercurrent attack of erysipelas. This fact impressed Dr. COLEY greatly, and he endeavoured to devise some means by which this sequence of events could be rendered available as a treatment for cancer. His first idea was, of course, to infect cancerous patients with the organism of erysipelas, but in practice several difficulties appeared. In the first place, it is not always easy to give rise to an attack of erysipelas, and in the second it is not possible to limit the virulence of the attack when it has once been started. Dr. COLEY therefore determined to employ the toxins instead of the living streptococcus. It has been shown, both clinically and in the laboratories, that the bacillus prodigiosus has in itself a curative effect upon tumours, and, moreover, that it intensifies the virulence of the toxins of erysipelas. Therefore, Dr. COLEY now employs a mixture of the toxins of these two micro-organisms. If we allow the correctness of the diagnosis of malignancy in the tumours treated, what results can Dr. COLEY show? Up to the present he has employed the treatment in nearly 500 cases, and of these only three died as a result of the treatment, though deaths have been recorded where the method has been employed by others. Of these 500 cases success seems to have followed the treatment in rather more than 50 cases, so that we may say that some 10 per cent. of the cases treated have had a successful result. The experience of Dr. COLEY shows that the failure which has resulted in the hands of many may be due to several causes. In the first place, it is fairly well established that it is only in sarcoma that satisfactory results have been obtained, for these toxins appear to be entirely useless against carcinomata. In the second place, many of the preparations of Coley's fluid which have been placed upon the market have not been made with the care and exactness which are employed in the preparation of the fluid used by Dr. COLEY himself. In the third place, the records of Dr. COLEY'S cases show that much perseverance and many injections are sometimes required to produce any evidence of improvement. Occasionally it has been owing to the wish of the patient himself that the treatment has been carried on until success has been attained. Fourthly, in many cases severe symptoms appear. Rigors, cyanosis, frequent and feeble action of the heart, with a temperature which may reach 105° F., will certainly tend to discourage all but the most enthusiastic believers in the efficacy of the fluid The reports of some of the cases successfully treated by Dr COLEY are very striking. In many of them several years have elapsed since the recovery, so that Dr. COLEY is justified in claiming that the result is permanent.

What, then, shall be said as to the value of the treatment? We feel that at present the attitude of the profession in this country should be strictly non-committal. We do not deny the records which have been presented to us. We willingly acknowledge the good faith, the energy, and the perseverance under difficulties which Dr. COLEY has shown in his elaboration of this method of treatment, and we consider that it deserves a thorough and careful trial at the hands of the profession of this country. It is no new method Some 16 years have elapsed since it was first brought forward by its originator, and during that time he has improved it until in his hands it appears to have reached some degree of exactness; and it is essential, if it is to receive a fair trial here, that the methods employed by Dr. COLEY should be adopted with the utmost exactitude. At the meeting of the Royal Society of Medicine it was urged that the method was unsatisfactory because we did not understand how it worked. This is an argument worthy of all respect from scientific men, but for practical purposes it cannot always be respected. If we are to be debarred from the use of a treatment because its *modus operandi* is unknown, of how many drugs in the pharmacopœia should we be deprived? The use of potassium iodide in tertiary syphilis and of colchicum in gout is absolutely emp[illegible] yet we are fully justified in employing these. And so it may well be with Dr. COLEY's toxins. We hope that the use of Coley's fluid will be carefully and thoroughly tested here, and we echo the wish of Mr. BUTLIN that Dr. COLEY could stay in this country for at least a year in order to show us how the method is employed, and how to attain the results which he himself has achieved.

The First Report of the Departmental Committee on Coroners.

THE Blue Book, recently issued, which contains the evidence given before the Departmental Committee appointed to consider the law relating to coroners and coroners' inquests and the practice in coroners' courts, contains much that is of interest to the medical profession. Before very long, presumably, the recommendations of the Committee will be issued, when it may be hoped that the course of politics will permit legislation to follow at no great interval. The law requires amendment, as all are aware who, as coroners, as medical practitioners, or in other capacities, have been brought into contact with cases of death where no medical certificate has been forthcoming, while the cause of death has had to be established in the interest of the public or of surviving relatives. At the intermediate stage which then ensues, and which precedes in some instances an inquest and in others burial without either a medical certificate or a public inquiry, the machinery has often failed to work smoothly, and the Committee has consequently had to concern itself largely with the possible amendment of the procedure at this point. The shortcomings have now been explained to a body competent to make suggestions of a practical character, and one result of the inquiry has been that the coroner's office and the inquest, including the coroner's jury, have received worthy vindication of their ancient dignity and usefulness from witnesses whose words are in every way entitled to carry weight. Their opinion may be summarised by saying that especially in cases where there is a suggestion of murder, manslaughter, or conduct deserving censure, it is of great importance that there should be an inquiry at which evidence on oath can be compelled, although no charge has been formulated against an individual, and at which statements can be admitted which would be excluded if such a person were being tried in accordance with the rigid laws of criminal evidence. The use of such statements, which might be kept back from those conducting an inquiry privately, is, of course, not to prejudice the guilty but to ascertain the truth as nearly as possible, to afford clues, and to suggest directions in which admissible evidence may be sought. With regard to the British jury, it has been spoken of by advocates in terms of turgid laudation as a "palladium" of our liberties, and it has been made, on the other hand, the object of censure and of ridicule not always undeserved. It may be admitted, moreover, that in coroners' courts not situated in such an exceptional area as the City of London the juries are hardly composed of the best educated and most intelligent of the community. Nevertheless, whether it be summoned to assist the coroner or any other judicial officer, the jury remains [illegible] fact," the most satisfactory tribunal that we are likely to obtain, in spite of the circumstance that its duties may involve the consideration of scientific testimony. There is, apparently, no desire on the part of lawyers, medical experts, or coroners who have given their evidence before the Departmental Committee to transfer the responsibilities of the men in the "box" to the coroner, either alone or in conjunction with a medical assessor. It is true that Professor H. H. LITTLEJOHN, with a combined experience of the English and Scotch systems, expressed an opinion in favour of the latter, and advocated an inquiry conducted privately by a trained legal official. His evidence was of a valuable character and will no doubt afford suggestions for improvement in matters of detail; but, on the other hand, Mr. A. J. PEPPER may be cited as a witness of weight who maintained his belief in the jury system, and other witnesses, including coroners, whose duty it has been to apply the existing machinery, took a similar view. Making allowance for the tendency which we must all have to trust to methods with which we are familiar, we do not think it likely that in this country the coroner's jury will be superseded by any other tribunal in the near future, although steps may be taken to render the enquiries more satisfactory to all concerned.

The method of summoning juries and the number of jurors desirable for practical purposes are discussed in the report, and other topics ventilated which are of special interest to the medical profession include the viewing of the body by the coroner and the jury. It is a little surprising to find a strongly voiced opinion in favour of retaining the practice under which a jury is compelled to inspect the body. Under present conditions, at all events where apparatus necessary for it exists, this is done without risk in possibly infectious cases and without any exposure of a distressing character. The reasons given for retaining the view, however, included the possibility of a juror making a valuable suggestion from the inspection (for which obviously something more than a glimpse of the uncovered face would be necessary), and also the danger of some deception, such as the substitution of another body, being practised. Mr. G. P. WYATT, a coroner of experience, was also of opinion that the necessity of inspection of the body by the jury afforded the coroner a tangible pretext for insisting on his right to have possession of the body without demur on the part of the relatives. The possibility of the coroner being given a discretionary power to order a view by the jury and of individual jurors being allowed to decline to avail themselves of the opportunity was considered, and this seems to us a fair compromise. Two important questions arose for the Committee out of the post-mortem examination—the first being whether the coroner should be empowered to order this before deciding to hold an inquest; and the second to whom he should intrust any post-mortem examination that he might consider desirable. Mr. R. HENSLOWE WELLINGTON may be mentioned as an advocate of the preliminary post-mortem examination. He put the number of inquests which might be dispensed with if the cause of death were to be thus ascertained at 40 per cent., and as it is admitted that an inquest often causes distress to the friends of the deceased, as well as public expense, it seems likely that the authority to make the order suggested will form the subject of a recommendation by the Committee. The question of who is to hold the post-mortem examination follows, and the opinions expressed were divided between the employment of an independent pathologist in all cases, and the alternative of his services being made use of at the coroner's discretion. The friction which has arisen in the jurisdiction of a London coroner owing to his practice in this matter will be remembered, and it will be interesting to see what the Committee will recommend. On the one hand, it is clear that the medical man who under the provisions of the Coroner's Act, 1887, now has the right to be ordered to make the post-mortem examination is perfectly competent to do so in a large number of instances, but in some others it would be better to employ a pathologist qualified by special training and practice for the purpose. If, however, the employment of the latter is not rendered obligatory a question necessarily follows as to how the coroner, particularly if he is not himself a medical man, is to exercise the discretion suggested. In this connexion it may be mentioned that several witnesses were asked as to the qualifications desirable for the holding of the coroner's office, and that Mr. HENSLOWE WELLINGTON was of the opinion that in country districts the legal qualification might be preferable to the medical, but that in large urban areas the coroner should be a "medically qualified lawyer with experience." These topics are likely, however, to be reviewed as a whole, the comparison of the English and Scotch systems, with the selection of desirable features from both, affording the most obvious method for obtaining that efficiency which we all desire to see—an efficiency which, be it remembered, must always fall short of perfection and, however generally satisfactory, can scarcely be expected to be beyond criticism.

The principal topics dealt with by the witnesses before the Committee, including those mentioned above, were propounded to them in a series of written questions addressed to them before they gave evidence, and a number of other points arising out of these were discussed. The fees of witnesses suggested dealing with those fees which should be paid but which are now unjustly withheld, when the deceased has died in a hospital and when the medical witness is a member of the staff of the institution. The Committee was reminded in an interesting piece of evidence by Mr. ISAAC BRADLEY, coroner for Birmingham, that this proviso is the survival of a clause to the same effect introduced into the Coroners' Act passed at the instance of Mr. THOMAS WAKLEY, the Founder of THE LANCET, early in the last century. It was then devised as a reservation in the nature of a compromise in order to induce Parliament to sanction the payment of any fees to medical witnesses, and its retention has been a matter of adverse comment ever since. Inseparably connected with the question of fees to medical witnesses properly so called is that of remuneration for medical men from whom coroners seek information when a death is first reported to them. We are not sure whether the Committee had this matter fully enough before it, and whether the evidence of one or two members of the medical profession conversant with the matter from recent personal experience might not be found useful. There are, however, more witnesses to be called, and the revision of the system of inquiry preliminary to holding an inquest or to dispensing with one must necessarily bring the subject under consideration. With regard to the scale on which medical fees should be fixed, as well as on other important subjects, the Committee had evidence from Dr. A. G. BATEMAN in his capacity of general secretary of the Medical Defence Union. His evidence, and that of several other witnesses, including Mr. CLINTON T. DENT, Dr. F. J. WALDO, and Mr. J. BROOKE LITTLE, a barrister, who gave an instructive historical synopsis of the history of the coroner's office, should interest medical men into whose hands the Blue-book containing it may fall.

We have not here gone into the evidence upon two subjects of rather disproportionate importance to which the Home Office called the Committee's attention after its appointment. These are deaths resulting from the administration of anæsthetics and the danger arising from the use of flannelette in articles of clothing. As to the latter, little was said of importance, attention being called to the provision for use of fireguards in the recent Children Act. As to the former, exhaustive and interesting evidence was given by an important series of witnesses, which will probably have as its outcome a recommendation as to the manner in which these deaths should be inquired into. This is, however, a matter which does not affect the general ordering of those duties which a long process of development has assigned to coroners.

Annotations.

"Ne quid nimis."

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE British Association for the Advancement of Science will this year hold its annual meeting at Winnipeg, in Western Canada, and a considerable number of passengers left British ports by steamer a week ago for the purpose of taking part in the proceedings. On the present occasion the association is making its third visit to Canada. At the first visit, in 1884, the meeting was held in Montreal, Lord Rayleigh being the President, while at the next visit, in 1897, the meeting was held in Toronto, with Sir John Evans as President. The proceedings will commence at Winnipeg on August 25th, Sir Joseph J. Thomson, Cavendish professor of experimental physics in the University of Cambridge, being the President. The work will be conducted in 11 sections, the subjects and sectional presidents of which will be as follows:—Mathematical and physical science (Professor Ernest Rutherford), chemistry (Professor H. E. Armstrong), geology (Mr. H. Smith Woodward), zoology (Mr. A. E. Shipley), geography (Colonel Sir Duncan Johnston), economic science and statistics (Professor S. J. Chapman), engineering (Sir William H. White), anthropology (Professor J. L. Myres), physiology (Professor E. H. Starling), botany (Lieutenant-Colonel D. Prain), with a sub-section on agriculture (Major P. G. Craigie), and educational science (Rev. Dr. H. B. Gray). Medical subjects treated from a clinical or therapeutic point of view are seldom, if ever introduced, but numerous questions of great medical interest have been from time to time discussed and it is understood that several papers of this kind will be read at the meeting. It may be almost taken for granted that Sir Joseph Thomson's presidential address will deal either with recondite questions of chemical physics or with the electrical theory of matter.

SYPHILIS BEFORE THE CONQUEST OF PERU.

THE question of the site of the earliest appearance of syphilis in the world has often been debated and will probably never be satisfactorily settled, the unenviable distinction having been variously claimed for Asia, Europe, and America.[1] A good deal has been written to prove that the Spaniards introduced the disease into Central and South America; and, on the other hand, certain authorities have believed themselves justified in claiming that Europe was free from it until it was introduced by the Spaniards on their return from the New World, through whom the Army of Charles VIII. of France, which invaded Naples in 1494–95, was infected, this being the first well recognised epidemic of the disease of which we have clear historical accounts. Though it is now pretty well ascertained that syphilis existed in Europe long previously to the return of Columbus, it is still very possible that his soldiers did bring back a virulent form of the disease. From the writings of the early Spanish missionaries and others it would appear that the disease called huanthi in the Peruvian Indian dialects was no new phenomenon, but had been well known among these peoples long before the conquest, and it is generally agreed amongst the medical men who have studied the question on the spot that this word is practically the native name for syphilis. It was recognised by the early missionaries that the lives of the Indians were exceedingly immoral, and that huanthi was spread in consequence of their licentious practices. It was even alleged that the disease was natural to certain animals, especially the alpaca, and that Indian herdsmen contracted it from them; but according to the most recent authorities it would appear that though the alpaca disease attacks the anus and genital organs and is highly contagious amongst these animals it is not communicable to human beings and is certainly not identical with syphilis. Its existence is, however, looked upon with special disgust by many merchants, so much so that they avoid all traffic in these animals and their skins, even though the trade is a lucrative one. A good deal of controversy has raged round the question of the nature of the terrible epidemic occurring in the neighbourhood of Quito which caused the death of the great Inca Huana Cápac. Cieza de Léon, writing about 1548, says that it was a pestilence of such terrible virulence that more than 200,000 persons perished. He describes it as small-pox, as also does Pedro Pizarro, writing in 1571. The Indian historian, Don Juan de Santa-Cruz, speaks of it as measles, and Pedro Sarmiento Gamboa as "a kind of fever (*enfermedad de calenturas*), which is thought by some to have been small-pox and by others measles." More recent writers have variously suggested malaria, leprosy, typhus, Peruvian verruga, and syphilis as being the true nature of this remarkable epidemic. The reasons adduced for some of these guesses—for they can hardly be much more—are not very convincing. With regard to syphilis, though that disease may not have caused the death of the great Inca, proofs are not wanting that it existed in the New World long before the arrival of the Spaniards. Very recently a young Peruvian medical man, Dr. Julio C. Tello, has published as a graduation thesis an account of a large number of human skulls which he has occupied his vacations in collecting from the tombs in the district of Huarochiri in the province of Yauyos, thus adding to the knowledge of these interesting memorials of an age long antecedent to the conquest obtained by Davila Briceño,[2] McGee,[3] Dr. Albert S. Ashmead[4] of New York, and Dr. Robert L. Nitsche.[5] Many of the skulls found by Dr. Tello presented exostoses, sometimes single sometimes multiple, of the frontal or parietal bones. In other instances there were perforations or loss of substance which may in some cases have been due to rude attempts at trephining. Dr. Tello thinks that though doubtless blows and wounds of the head were frequent enough amongst the old Peruvians many of the lesions presented by the skulls in his collection were due to a combined effect of the specific disease and the traumatism. This immense collection of pre-historic remains, which has been given to the University Museum in Lima, has already been an object of great interest, pathological and antiquarian, and the energetic young investigator has found no lack of professors and other medical men who are in agreement with him as to the probable syphilitic nature of many of the pathological conditions presented in the specimens.

"FOR PROFESSIONAL SERVICES RENDERED."

AN anonymous correspondent, recently writing to the *Stage*, called the attention of "The" Profession to which he belongs to a grievance which he alleges is felt by many medical men towards certain of his brethren. He premises that "a large number of the foremost members of the medical profession as well as many general practitioners, have been kind enough to give their time and services to the members of the Actors' Association," and discusses the obligation which rests upon the beneficiaries of this concession to render something in return. He goes so far as to state that "the original undertaking was that these honorary physicians and surgeons should receive, as a sort of *quid pro quo*, in no way commensurate with their services, the courtesy of free admission to the theatres in London and the provinces." His point is that this unwritten contract has not been fulfilled by his profession, and that "complaints are constantly being made by doctors in consequence." He asks that a definite policy may be made clear as to whether the medical men in question are to be accorded this honorarium in future or not, and in the latter case he prophesies that "it is natural and reasonable to anticipate the eventual collapse of a hitherto inestimable benefit available to members of the Actors' Association." The communication, coming apparently from an actor, is worth consideration, and in discussing it we do not wish to narrow the principle involved to the application of any particular case, but rather to inquire whether medical men who voluntarily give their services with their eyes fully open to the gratuitous nature of the arrangement have a legitimate grievance if they get no more substantial return than the blessing which rests on the giver. We are inclined to think that they have no grievance, and for this reason. If they agree to treat people without fee, the inference is that those particular people are for some cause unable to pay a fee at all commensurate with the nature of the services rendered to persons of their own station in life. Now every busy medical practitioner comes across a large number of cases to which this description unfortunately applies, notably amongst the professional and "retired" classes, whose antecedents and appearances prevent them from applying for hospital relief, even if their pride would allow of it, but who can only just make both ends meet in the ordinary course, or perhaps cannot even do that, and who are absolutely unable to bear the financial strain of a time of sickness without the generous assistance which they often receive from their medical attendants. The reason of this generosity is, of course, that the traditions of medicine are those not of a trade but of a liberal and humane profession, and although we know full well that there are a number of comparatively well-to-do people constantly seeking the services of medical men who are ready to exploit this professional tradition in the shabbiest manner, yet we should be very sorry to think that their selfish greed should ever suck the well-springs of medical compassion so dry that they should cease to flow for those in true need of them. But if it is sometimes the privilege of the medical man to give freely of his best, it is no less his duty to withhold gratuitous attendance from those who are properly able to pay for it, and the only general rule which he can follow safely is to decide every case on its own merits. We will put aside as a special case the mutual gratuitous attendance that is customary amongst medical men and is generally extended to their immediate families, only remarking that the extension in question is sometimes stretched beyond its fair limits, and we will not discuss at present the enormous amount of free medical work that is done every day amongst the working-classes and the poor, for this falls under a somewhat different consideration from the case of the professional classes Amongst these there are two which have been favoured with so much gratuitous medical attendance in the past that we understand that not a few of their members have come to regard the free services of a medical man almost as one of the prerogatives of their calling, or who would at least be unpleasantly surprised to receive a normal account from their medical attendant. In thus alluding to the Church and the Stage we do not wish it for a moment thought that we deplore the custom which has led our own profession to offer generous treatment to the poorer actors and actresses, and especially to ministers of religion. The miserable stipend of the hard-worked curate with a family is only more notorious than the financial disabilities of the actor who has not "arrived," and the very genuine gratitude of many a poor clergyman or player to his medical benefactor—who has himself, perhaps, found the struggle for existence none too easy—must often have gone far to reward the compassionate practitioner for doing what he could for a fellow creature in distress. It may well happen that if the grateful patient attains to an unexpected success he will make it his business to requite the man who helped him in some tangible manner; but the essence of an act of fine charity seems to us to be tainted if it be bestowed by the medical man with the proviso—implicit or explicit—that he should receive payment in kind. If he wants to make a charge let him make one, or refuse to treat the case, as he may quite properly do, but by all means let him avoid the impossible attitude of doing a man a good turn "for nothing," and then feeling aggrieved because he has got nothing for doing it. To return to our original instance. Whether the definite arrangement exists between the Actors' Association and its honorary medical officers which the *Stage's* correspondent describes, we have considerable doubts. If it does we can only wonder at the influence which that association commands in being able to pledge the credit of the proprietors and managers of the theatres throughout the country to supply free seats to medical men who ask for them. We certainly are not aware that medical men are in the habit of applying for free seats. At the same time we are quite sure that the more prosperous members of the dramatic profession who can afford to pay their lawyers and their tradesmen to the full would not seek to evade the payment of their medical attendants, who would be very ill-advised not to send in their professional accounts to any patient who can obviously afford to pay it, whatever be his calling. Whilst free medical work may be sometimes properly done for hardworking or retired professional men with an income disproportionate to their legitimate needs—and especially to actors or clergymen, who are conspicuously ready to give their services to help other people—no return should be looked for in consideration of what is simply an act of mercy. We can see no reason why a rector with a comfortable living, and perhaps private means as well, or a prominent actor earning his £10 or £15 a week should not pay for medical attendance exactly the same fees as would be expected from a soldier, an architect, or a lawyer enjoying the same income and subject to the same kind of expenses.

THE DOSAGE OF DRUGS IN RELATION TO BODY WEIGHT AND SURFACE.

IN the *Bio-chemical Journal* for July Professor Benjamin Moore, professor of bio-chemistry in the University of Liverpool, argues on the fallacy of stating the dose of a drug in relation to the body weight of the subject of treatment. He considers that, quite apart from idiosyncrasies and alteration in the species of animal, this method of stating dosage is based on a wrong principle. Many drugs, even in the same species of animal, act upon two individuals of different size proportionately to their body surfaces, or, in other words, proportionately to the two-thirds powers of their weights. For example, the dose of many drugs that can be given to infants to produce a given therapeutic result is often many times larger than the proportionate dose for an adult on the basis of the body weight. Apart from a few cases of idiosyncrasy, as with morphine, it is usually found that the balance is in the opposite direction. Thus, an adult weighing 150 pounds cannot be given 15 times the dose for an infant weighing 10 pounds, but more nearly a dose of six times as much, which is the two-thirds power of the ratio in the two weights. Professor Moore further claims that there is a limit to our power of applying therapeutic agents against disease in larger animals, and that a cure may be effected with ease in smaller animals, but not in large animals or in man, simply because of their greater size, and not because of any peculiar sensitiveness to the drug. In support of these contentions he cites the case of atoxyl, a drug which easily cures trypanosomiasis in small animals, such as the mouse. The difficulty of effecting a cure, however, increases with rabbits, while with men and the larger animals the difficulty is enormously greater, as the trypanosomes can scarcely be driven out from the circulation by such sub-lethal doses as it is possible to give. Bearing these facts in mind, Professor Moore sought to find a physico chemical basis which might afford an explanation. A study of the action of arsenic, antimony, atoxyl, and the soluble salts of bismuth, iron, and other metals led him to the following conclusions: 1. In the case of substances which act by stimulation or inflammation of surfaces, such as the intestinal tract, the maximum dose is proportional not to the body weight but to the two-thirds power of the body weight. 2. This leads to important differences in dosage in man and large animals. 3. It also shows that the possibilities of treatment are diminished by natural means in man and large animals, which have naturally less intestinal and other surfaces per unit of weight Accordingly they can only take up proportionately less drug, and if any remedial substance is manufactured by the surface cells they can only manufacture relatively less than the smaller animal. 4. In general terms it may be said that the uptake and output of poison or infection are relatively more rapid in the child, and in small animals, which are on this account more susceptible to the onset of infection, and at the same time have more power of recuperation when infected. Professor Moore suggests that for the great majority of drugs the method of stating dosage as so much per kilogramme should be abandoned. It is preferable to determine the dose for an animal of an observed weight by taking the two-thirds powers of the two weights and calculating the dose for an animal weighing one kilogramme, stating the dose as for a one kilogramme animal and not as per kilogramme of body weight. From this dose the dose for a man of average weight, say 64 kilogrammes, can readily be deduced. It is the dose for the one kilogramme animal, not multiplied by 64, but by the two-thirds power of 64, which is 16. Hence it is obvious that the usual method of calculating the dose gives a result *four times too high*. This new formula is interesting and perhaps accounts for the fact that in human therapeutics the dose for light and heavy persons does not rise and fall in proportion to their weight. The heavier person requires a slightly higher dose, but not proportionately to his greater weight.

THE SIXTEENTH INTERNATIONAL MEDICAL CONGRESS: THE OFFICIAL USE OF THE ITALIAN LANGUAGE.

THE general secretary of the approaching International Medical Congress, which will open at Budapest on August 29th, informs us that 3000 members have already expressed their intention of attending and that a further 1000 may be expected. Up to August 11th the list of medical men from different countries who have subscribed to the membership is made up as follows: Argentine Republic, 35; Austria, 188; Belgium, 43; Bosnia-Herzegovina, 7; Brazil, 22; Bulgaria, 17; Chili, 4; Cuba, 6; Denmark, 8; Egypt, 21; France, 257; Germany, 218; Great Britain and colonies, 92; Greece, 16; Holland, 31; Hungary, 855; Italy, 145; Japan, 24; Mexico, 3; Monaco, 1; Norway 2; Portugal, 28; Roumania, 10; Russia, 172; Servia, 4; Spain, 64; Sweden, 4; Switzerland, 23; Turkey, 17; United States, 164; and Uruguay, 2. 656 ladies intend to accompany these congressists. The programme of fêtes and receptions will appear in the first number of the official journal of the Congress, which will be distributed to members of the assembly on August 28th. Besides the "soirée of welcome" the programme will include a reception at the Royal Hungarian Court and evening entertainments given by the President of the Congress, the municipality of Budapest, the Presidents of the 21 sections, and the Ladies' Committee. It may be well to clear up some misconception concerning one of the official languages to be used at the Congress. For some time past the Italian journals, professional and lay, have been under the impression that their country's language would be excluded from the proceedings of the Congress and that Italy's representatives would be able to intervene in the discussions only in German, English, or French. How that impression can have been formed it is hard to say, but that it undoubtedly existed has been but too evident from the spirit—not quite "fraternal!"—in which Italy has been discounting in advance the importance of the Congress and the value of its contributions to the cause of medicine, scientific and clinical. Something of the resentment with which Italians have been contemplating the attitude of Austria—not Hungary—towards her academic claims at Innsbruck and Trieste, nay, in Vienna itself, may have coloured the comments above referred to, and at one time it appeared quite possible that not only the Italian language but the Italian delegates would [illegible] pation [illegible] by the correspondence now made public between Professor Temesvary, representing the University of Budapest, and Professor Luigi Maria Bossi, representing that of Genoa. "The Italian language," writes the former gentleman, "will be equally recognised at the Congress with our own. The Italian 'reports' are already printed and distributed in the Italian language. We Hungarians love and esteem our Italian colleagues because on the battlefield of science our cause, our ideals, and our enemies are the same. We cordially await the arrival of our Italian brethren." It should be remembered that Article 16 of the constitution of the Sixteenth International Medical Congress stipulates that "the Italian language is recognised in the discussions of the Congress as on absolutely the same footing with the French, the English, and the German." The organising committee of the next Congress has thus taken full account of the claims of Italy—claims, it may be added, which have been ignored in recent congresses. We are informed that His Excellency Signor Rava, Minister of Public Instruction in the Italian Government, has received by telegraph from Budapest a confirmation of the admission of his country's language to equal rights with its three sisters at the coming Congress. So "all's well that ends well."

PLAYING WITH SAND.

THE amusement which children find in making "castles" with sand on the seashore, in digging trenches and pits, and tracing designs on the alluring surface is innocent enough and serves to keep the youngsters occupied and to give them exercise in the healthy environment of sun and fresh sea air. A somewhat similar end is gained by providing sand heaps inland, in public parks, and in various open spaces, and as a matter of fact such heaps of sand are a source of joy to many children. It would be a pity to kill such joy, for the lot of the poor city child is, as a rule, a poor one, but we would suggest that some attention be paid to a certain insanitary aspect of these inland sand games. It must be remembered that the sand of the seashore is continuously washed by an advancing and receding sea, and so is made clean every tide. But that is not the case with the sand heap at home, which, after the play of a few weeks, becomes very dusty, and this dust during the play is scattered in all directions, and no doubt a good deal of it is swallowed and some inhaled. Infection may follow, for no one could be bold enough to say that the sand after days of use would be free from infective material. It would be a great gain if the sand could always be kept damp and free from dust, but it would be better still if damping could be associated with the application of an inoffensive antiseptic.

THE USE OF CASIMIROA EDULIS AS A HYPNOTIC.

IN *L'Union Pharmaceutique* for July M. Albert Robin and M. A. Coyon call attention to the value of the fruits of *Casimiroa edulis* as a hypnotic. It is a Mexican plant, of the natural order Rutaceæ, and has been employed with success in South America for many years as an analgesic, sedative, and hypnotic. M. Robin and his colleague obtained a supply of the drug, and after a trial extending over two years they speak in terms of praise of its hypnotic and antispasmodic action. They used it in the form of a fluid extract, in doses of one to two teaspoonfuls, and observed that its administration was followed in two or three hours by a calm sleep, free from nightmare, and resembling natural sleep. The effect lasted about five or six hours and the patients on awaking did not suffer from headache, fatigue, or nausea. On account of its harmlessness in these doses they recommend the use of the drug in renal and nervous affections, particularly in old people. It is not advisable to give higher doses than two teaspoonfuls, as the drug produces toxic effects in large doses. According to some Mexican writers it exerts a paralysing effect on the respiration, although M. Robin and M. Coyon were unable to confirm this statement. They noticed, however, a paralysing action on the cardiac muscle, which would contraindicate its use in cases where the myocardium is injured. In the *Press Médicale* of June 30th M. Chevalier suggests that casimiroa has a selective action on the brain, rapidly causing a depression of the intellectual and sensory functions, and therefore deadening the sensation of pain. Large doses produce almost complete anæsthesia, which persists while the grave symptoms of intoxication remain. The drug lowers the temperature, arrests the respiratory movements, and diminishes the number and the energy of the cardiac movements. It also lessens the blood tension and produces marked peripheral vaso-dilatation.

DANGEROUS HAIR-WASHES.

No one who read Dr. Augustus D. Waller's communication to THE LANCET of August 7th, p. 369, in which he demonstrated the very toxic nature of carbon tetrachloride, can doubt that such a readily vaporised and poisonous substance ought not to be employed in any toilet operation. Dr. Waller examined the contents of a hair-wash consisting largely of this substance, though mixed with carbon bisulphide, another poisonous gas, by means of unimpeachable physiological tests such as he has proved of great service in the estimation of the relative toxicity of anæsthetic substances. Dr. V. H. Veley amplified these results by a chemical analysis, and the verdict against the hair-wash was final. If further proof be required it is afforded by a letter from Dr. J. E. Sandilands, which we print on another page. The question asked last week by Sir William Collins of the Home Secretary in the House of Commons, and recorded by our Parliamentary reporter, was the natural sequel of these investigations. Mr. Gladstone's reply to a catechism concerning the recent death of a lady from the effects of the hair-wash, the danger of that substance, and Mr. Gladstone's intentions as to stopping its sale, was written as follows:—

> My attention has been called to the use of tetrachloride of carbon as a hair-wash, to the very great danger involved, and to the death referred to by my honourable friend. I am informed by the Privy Council that tetrachloride of carbon is not a poison within the meaning of the Pharmacy Acts, and there are, therefore, no restrictions as to its sale. As regards the steps to be taken in the matter, I can only say that the Director of Public Prosecutions has the question of a prosecution now under his consideration.

We presume that Mr. Gladstone was using his best endeavours in the public safety and can only regret that he is not empowered to do more to enforce it, for if there ever was a case for the issue of an administrative order we should have thought this to be one. There is something sadly lacking in the machinery of Government if, when it has been found that a powerful poison is being commercially used in a manner dangerous to human life, the Government, though well aware of its nature, has no power to stop its sale because it is not a poison "within the meaning of" an Act. It is conceivable that an extension of this principle to other unscheduled poisonous substances might lead to even worse disaster. In the meantime we are informed that the use of the poisonous hair-wash has not been discontinued, and even though the Public Prosecutor intervenes in any particular case, the resulting verdict will apply to that case alone. In the meantime we would point out that under Section 2 of the Poisons and Pharmacy Act of 1868 which was not repealed by the Amending Act of last year, the Privy Council has power to declare carbon tetrachloride to be a poison "within the meaning of the Act," on the recommendation of the Council of the Pharmaceutical Society of Great Britain. We trust such a recommendation will be forthcoming.

MENINGITIS DUE TO THE TYPHOID BACILLUS IN ENTERIC FEVER.

AT a meeting of the Société Médicale des Hôpitaux of Paris on July 16th M. Claret and M. Lyon-Caen reported a case of enteric fever with the rare complication of meningitis due to the typhoid bacillus. A woman, aged 23 years, was admitted into hospital with the general and abdominal symptoms of enteric fever on April 20th. She had suffered from headache and fever for 10 days and was very prostrate. She was found to have a furred tongue, dry at the tip and edges, gurgling in the right iliac region, palpable spleen, bronchitis, and constipation. The temperature ranged from 103·3° F. in the morning to 104° in the evening. Rose spots subsequently appeared and the serum reaction was positive in a dilution of 1 in 100. On May 1st the patient complained of violent headache, and there was ptosis of the left upper lid. On the 3rd the signs of meningitis were complete—rigidity of the neck, Kernig's sign, inequality of the pupils, an irregular pulse of 110, and vomiting. Lumbar puncture showed no increased intra-meningeal tension and yielded 15 cubic centimetres of clear albuminous fluid. The fluid was centrifugalised and the deposit showed 60 per cent. of polynuclears, 25 per cent. of mononuclears (lymphocytes and large mononuclears), and 15 per cent. of red corpuscles. No bacilli were seen. On May 4th the rigidity of the neck was a little less, lumbar puncture was again performed, and the typhoid bacillus was cultivated from the deposit in a state of purity. The patient was treated with cold baths, and except for an intestinal hæmorrhage two days later her condition remained the same until May 8th, when she was weaker and had violent nocturnal delirium and incontinence of urine. On this day lumbar puncture yielded clear fluid containing lymphocytes and some red corpuscles; the typhoid bacillus could not be cultivated from the fluid, which agglutinated a young culture of the typhoid bacillus in a dilution of 1 in 20, while the blood serum agglutinated it in a dilution of 1 in 100. Recovery gradually took place. M. Claret and M. Lyon-Caen were able to find only 12 recorded cases in which during life the typhoid bacillus was found in the cerebro-spinal fluid by direct examination (four cases) or cultivated from it (eight cases) in meningitis in enteric fever. In only two cases was the fluid described as purulent; in one it was described as opalescent, in three as slightly hæmorrhagic, and in seven (including the above case) as clear and limpid. Only one writer, Nieter, investigated the agglutinative power of the cerebro-spinal fluid. The researches of Concetti, Widal, and Sicard show that in ordinary enteric fever this power is almost always absent, however intense be that of the blood serum. In the above case, as has been shown, it was feeble. It is interesting to compare this weak agglutinating power of the cerebro-spinal fluid with its bactericidal power, which, according to Concetti, is constant. Another interesting point is the duration of the infection of the cerebro-spinal fluid. In two cases the bacillus was found after two punctures made at an interval of eight days, but was absent when a third was made eight days later. In another case the first puncture, made when prostration was the only sign of meningitis, yielded clear and sterile fluid; a fortnight later the fluid was purulent and contained the bacillus. In the above case the second puncture, made four days after the first (which showed a polynuclear reaction and the bacillus) yielded sterile fluid showing a predominant lymphocytosis. Comparison of the result of cultures made from the *blood at the same time as cultures from the cerebro-spinal* fluid would be of interest. But only one case is recorded—by Jemma—in which the culture made from the blood was negative, while that from the cerebro-spinal fluid was positive. From the clinical standpoint three principal forms of meningitis could be distinguished in the 13 cases. In the first group the meningitis usually supervened from the fifteenth to the twentieth day, more rarely during convalescence. The course of the fever was a little modified; its classical signs, especially the rose spots, were a little late in appearing, and constipation was usual and gave place to diarrhœa only towards the end, and finally the serum reaction was delayed. This form occurred in nine cases, of which four were fatal. In the second group (two cases) symptoms of meningitis suddenly occurred without anything to suggest enteric fever, and the diagnosis was made only by culture of the cerebro-spinal fluid obtained by lumbar puncture, which was confirmed by the appearance of signs of typhoid fever about the tenth day. Both patients recovered. In a form still more difficult of diagnosis (two cases) the course resembled that of cerebro-spinal meningitis and no signs of enteric fever appeared. The diagnosis could be made only by culture from the cerebro-spinal fluid. The meningitis constituted the sole reaction of the organism to the bacillus. One of these cases was fatal.

THE ITALIAN OFFICIAL REPORT ON MALARIA.

THE highest tribunal of hygiene in Italy—the "Consiglio Superiore della Sanità"—has just been considering the report drawn up by Professor Badaloni of Naples in "La Lotta contro Malaria," and, on the motion of Dr. Santoliquido, Director-General of Public Health, has ordered it to be made *publici juris*. The report, based on inquiries extending over the period when State intervention against the malady was initiated to the present year—from 1902 to 1909—gives signal proof of the efficacy of the measures adopted, with exceptions to be noted presently. First in importance in diminishing the mortality from the disease must be placed the diffusion, at a moderate price, of good preparations of quinine, and the supply of these gratuitously when beyond the purchasing power of the individual. This gratifying diminution was obtained in regions to which the "bonifiche idrauliche e telluriche" (reclamation of the soil by hydraulic and agricultural methods) had not been applied, a fact, however, which by no means excludes the inference that the result would have been still more gratifying in regions where the methods indicated had been put in practice. The tenure of the report makes it evident that "hydraulic and telluric bonification" must henceforth go hand-in-hand with the cure till, *viribus unitis*, *the poison is stamped out altogether*. No real influence, proceeds the report, in the diminution of mortality from malaria can be attributed to the use of the "protezione metallica" (wire gauze). Just as little can be credited to the destruction of "zanzare" (mosquitoes). This finding will certainly be regarded as retrogressive, but it is of interest in view of a recent article in THE LANCET,[1] entitled "Does Malaria ever Occur Epidemically Without the Agency of Anophelines?"—a question which, it is well known, many Italian experts are still prepared to answer in the affirmative. Another finding, vindicated at length in the report, is the doubtful efficacy of the "profilassi chinica" (the prophylactic administration of quinine). The anti-malaria cure must be practised either in the "epidemic period" or (if attempted prophylactically) in the "inter-epidemic period" and ought *to aim at the "completo bonificamento umano"* (at the complete physical rehabilitation of the individual). A final finding makes it "indubbio" (certain) that the influence of the preparations of quinine associated with the use of the same medicament as an aid to the "bonificamento umano" is the practice to be pursued in combating the disease when present. The special documents, in the form of reports by experts on the malaria-haunted regions of Italy, as to the efficacy or inefficacy of the measures above indicated, will be read with interest as illustrating and fortifying the findings of Dr. Badaloni, whose "Relazione" is countersigned by all his colleagues on the commission, to wit, Baccelli, Golgi, De Giaxa, Korner, and Ferrero di Cavallerleone—names in themselves a guarantee of the competence and the impartiality with which the inquiries have been conducted and the conclusions formulated.

THE USE OF FORMALDEHYDE FOR PRESERVING MEAT.

THE attention of the Local Government Board has been drawn to the increasing use of preparations of formaldehyde by dealers in perishable foods, the gas being employed in meat safes or as a fumigating agent in the holds of ships in which chilled meat is brought to this country from South America and elsewhere. In a recent report to the Board by Dr. G. S. Buchanan and Dr. S. B. Schryver it is presumed very logically that when formalin or its preparations are offered to, or used by, dealers in perishable foods the intention is to employ the solution as a disinfectant or deodorant so, in fact, as to conceal incipient decomposition and to hide any smell of staleness or putrefaction. The trade appear to regard formaldehyde as a substance which "arrests decay," which is "non-poisonous and non-acid," and which therefore is "of the greatest importance to poulterers and all dealers in perishable articles of food." It appears, further, that special safes are recommended for the treatment of provisions the keeping powers of which may thus be increased in hot weather. Since formaldehyde is a deodorant as well as a disinfectant its use is no doubt recommended also to remove taint. According to the report referred to, the food-stuffs to be treated are placed on shelves or hung on hooks in a safe into which a current of formaldehyde gas is discharged from an apparatus attached near the floor. *Pastilles of paraformaldehyde* are used in this apparatus. The heat of a lamp serves to decompose the pastille into formaldehyde gas. The foodstuffs are left in contact with the vapour in the closed safe for 20 minutes or so and the excess of formaldehyde is then removed by passing a current of air through. For the treatment of milk a sieve is employed which is placed in the roof of the apparatus. The milk passing through the sieve is divided into drops which come into intimate contact with the formaldehyde gas. There can be little doubt that this apparatus is likely to become popular, especially in hot weather, with the proprietors of cafés, restaurants, and similar places. The question remains as to whether the adoption of this method is likely to be fraught with menace to the health of the public. There are substantial reasons, the representatives of the Local *Government Board think, for objecting* to the presence of formaldehyde in foodstuffs, for it has been definitely stated that it may retard digestion even when present in the food in comparatively large dilution, while it is well known that it readily combines with the protein constituents of foods, forming a compound which is less digestible than the original substance. These objectionable properties were recognised by the Departmental Committee on Preservatives and Colouring Matters in Food in 1901, which recommended that the use of formaldehyde or its preparations in foods and drinks be prohibited absolutely. It has been assumed, however, that the penetration of the aldehyde into foods by simple fumigation in a ship's hold or in a domestic safe is negligible, and that no more than a harmless, or even a desirable, surface disinfection is accomplished. From the results of an experimental inquiry made by Dr. Schryver, however, it seems pretty clearly demonstrated that it was possible to recover formaldehyde not only from various parts of a forequarter of beef taken from the hold of a vessel which had been treated with formaldehyde gas, but from parts below the surface, especially where the muscular tissue was not covered by connective tissue or fat. Portions of the beef were also tested after ordinary cooking, when it was found that boiling and roasting appeared to reduce or even to remove the formaldehyde, but grilling appeared merely to make the formaldehyde retreat further into the substance of the meat. As Dr. Buchanan points out, the results have a special significance as regards meat which is treated in a formaldehyde safe, for they indicate that articles such as minced meat, fish, kidneys, and other foods which expose a large surface in proportion to their weight cannot be subjected to this form of formaldehyde fumigation without absorbing relatively large quantities of this disinfectant. It is evident from Dr. Schryver's results that special methods are required if the addition of formaldehyde to meat is to be detected with certainty—methods, in fact, which must be applicable not only to the estimation of the free aldehyde but also of the polymerised product and of the aldehyde which has entered into combination with the food constituents. This fact probably accounts for the statement by a firm supplying formalin safes that no disinfectant can be discovered in meat which has been treated by the process. It seems logical to conclude also that formaldehyde is ineffective as a preservative unless present in a quantity in excess of that which possibly may be decomposed by tissue.

---

[1] THE LANCET, July 24th, 1909, pp. 237.

IN the column dealing with the Services we publish the outline of a scheme submitted by the Army Council to the various Territorial county associations in England and Wales concerning the formation in connexion with each association of voluntary aid detachments for the treatment and transport of the wounded in the event of an invasion of the country. The scheme has been elaborated with the coöperation of the Council of the British Red Cross Society, the members of which are allotted an important share in the proposed organisation. The scheme is noteworthy by the fact that it provides for the permanent establishment of detachments of medical and other women trained in Red Cross work in a position which will give them a definite function in the Territorial Army.

RUSSIAN MILITARY TUBERCULOSIS SANATORIUM IN FINLAND.—According to the Finnish journal, *Birsch. Värd*, the Russian Ministry of War is erecting in the heart of the Finnish pine-forest domains, a tuberculosis sanatorium for the men of the Russian regiments of the Guards, capable of accommodating 500 patients.

LUNACY IN MANCHESTER.—Of the large number of lunatics certified last year Manchester contributes its full share. The total for England and Wales is 128,787, and the rate of increase since 1905 is over 2000 a year. Manchester heads the list of the county boroughs with an increase of 98. The total number of lunatics chargeable to the union and parish rates in Manchester was 2159, and chargeable to county and borough rates was 52, the total being 2211, of whom 1094 were females.

MOTORING NOTES.

By C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

Some Suggestions as to the Care of the Car in Hot Weather.

THE recent and late arrival of summer, unattended by fanning breezes, makes roadside stops the reverse of desirable, and as with the present temperature the wax insulation and filling-in of coils is liable to melt, possible short circuits in engines with coil ignition can be avoided by protecting the coil boxes with asbestos sheeting. Another advantage at this time, when even the effort of pulling the starting handle round to start the engine is exhausting, is to have trembler coil ignition, as with this form the motor will frequently start on the switch. Magneto-fired motors can now be started by merely pressing a button. This device is put on the market by the Aston Motor Accessories Company, Limited, of Birmingham; it consists of an accumulator the current from which is made to pass through the magneto-armature in the correct direction, so that it does not hurt the magnets, but rather strengthens them, and, of course, it causes a spark in the cylinders, so that pressing the button starts the engine. This invention is very simple and can be fitted to any existing magneto. Other points worthy of consideration are the lubricators, the carburettor, and the tyres. With all forms of lubrication it is important to bear in mind that in hot weather the oil is thinner and therefore drips more readily; so to obviate smoky exhaust, and possible sooty plugs, it is as well to regulate the drips that they may not be too generous in the quantity of oil they deliver to the engine. Petrol, too, will vaporize more quickly, so if possible the air inlet should be opened more fully, and if this is not practicable a Rotherham lubricator can be screwed into the side of the air intake-pipe, which can be tapped to receive it; if the lubricator be then opened more air will thus enter. Another device is to drill a hole covered with gauze in the pipe, and if this be done a ring can be fitted to obliterate the aperature on the return of cooler weather. With the heat and dust it is possible that foreign matter may enter and either block the gauze over the petrol inlet at the float chamber or, if a strainer is not fitted, the jet itself may become choked. A halt to remove and clear the jet is not inviting and it is well to obviate it by fitting a gauze strainer where the petrol pipe enters the float chamber. If such a foreign-body filter be employed prior to leaving home it is as well to make sure that the gauze is not rendered impervious to petrol by dust. Personally, I am an advocate for the pumping hard of tyres, a fully inflated inner tube has, I am sure, a longer life; still air expands more in the sun than in the cool garage, and this should be borne in mind when seeing to the tyre pressures before starting out. A burst cover means, even with a Stepney, some minutes' delay, and with the thermometer at 84° F. in the shade putting on that useful and excellent invention does not conduce to a proper appearance for the paying of professional calls. A pressure of from 75 to 80 pounds will be ample for the average-sized driving wheel tyres and less for the front wheels.

Hints on Driving a Motor-car.

Most purchasers arrange, when buying a car, that a professional should accompany them when they take delivery, and anyway give them a few hours' instruction in the management and driving. They thus learn where the petrol tank is, the importance of using a strainer when replenishing so as to prevent the entrance of any foreign body, then to inspect that the water-tank is full and that the circulation is clear, the lubricating reservoir full of suitable oil, the grease cups filled and screwed on tightly, and that the crank case, gear box, and differential chamber contain the requisite lubricant. Retarding the spark and observing that the gear lever is in the neutral notch, the engine is started, and mounting, the driver's seat is taken, the ignition slightly advanced, the clutch depressed, the throttle opened, and the gear lever advanced into the first speed, and, taking care that the brake is off, the clutch is gently let in, and then away should glide the car. I have heard what I looked like myself some ten years ago when first I essayed to command an automobile, and I have seen and helped many other beginners since. The grave face shows that the importance of the occasion is realised; a wide berth is given to the curb and passing traffic, and with scrupulous care the amateur keeps to his correct side of the road. Joy and elation are experienced when the "Thing" goes; it is taken out for a few miles, turned round where the road is wide and no one is about, and then driven home. Probably after a short trip on the first speed the clutch will be depressed and the second gear brought into mesh and [illegible] and should give confidence to the driver, though this should not be abused, as the frequent use of the brakes is bad alike for tyres and machinery. Then the car may be taken to a hill, letting the sprag, if there is one, down, and when the engine begins to slacken, declutching and dropping into a lower gear. Changing down as well as into a higher gear is a mere knack; all that is needed is that the teeth of the wheels which are to be brought into mesh should be in such a position that the teeth of one wheel are just opposite the spaces in the pinion into which they are to slide, as otherwise grinding, and maybe even a broken tooth, may result. A careful driver, after declutching gently, moves the speed lever, and can tell by the feel when the spaces and teeth coincide and then will engage them. It is important for the would-be chauffeur to learn to do this, and, as I have already said, it is merely a knack, which with a little practice and patience can soon be acquired. It is as well to first try on the level, for if the gears are missed on a hill, if the sprag jumps the car may run backwards; still, even then an accident should not result if the brakes are put on quickly, and if they have been kept adjusted and act. Having learnt how to drive forward, and how to stop suddenly in cases of emergency and gently for ordinary pull-ups, reversing and driving backwards should be attempted. It has to be remembered that the car must be brought to rest and, of course, the clutch withdrawn before the gear lever is drawn into the reverse, and then, looking backwards, reversing may be practised. I believe that it is best to learn driving on one's own car, and, of course, those who feel nervous can usually arrange with the makers of whatever car they select that an instructor should remain with them for some days, or any way until they feel confident. Those who desire instruction prior to purchasing will find that most dealers are now prepared to give lessons. In London driving lessons are given by capable instructors to members and servants of members by the Royal Automobile Club. Driving lessons, as well as instruction in the mechanism, &c., can also be obtained at Motor Schools, Limited, Heddon-street, Regent-street, London, W.

Some excellent road maxims have been compiled by the editor of the *Car*. He first advises motor-car drivers always to assume that other road users may do the wrong thing, and this is very true, for pedestrians often hesitate and try several courses, and as to taxi-cab drivers you may expect anything. From experience in driving about town, I know that these individuals will pass over and turn off without holding up a hand; also that they will cut in to their own side again much too soon after overtaking another vehicle. Another maxim is that it is the driver's business, not the other man's, to avoid danger. This aphorism, too, might with advantage be impressed on taxi-cab drivers. Of course, in all cases of accident, irrespective of whose fault, the motorist should stop and render any help he can; and for his own sake, in view of possible future accusations or proceedings, he should obtain the names and addresses of any witnesses. It is also advisable to drive slowly when approaching cross roads, passing schools or churches, or turning a corner. However good the brakes may be, it is not always easy to pull up dead at a moment's notice if the car has any way on it. Therefore it is not wise to follow closely in the track of another vehicle, as in the event of that vehicle suddenly stopping it may be difficult to avoid a collision. Always hold up the hand when stopping, and when turning off hold out the hand on the side on which you intend to turn off. Use great caution on approaching any stationary vehicle, especially trams, as they may obstruct from your view a pedestrian or a passenger alighting. There is a regulation, too, that such vehicles are to be passed on the right or off side, but I understand that this will shortly be amended. A temptation, and one to which I fear that in my earlier days I used to yield, is to pass a street refuge on the wrong side, so as to get by a string of slow-moving carts, but the risk makes it really not worth taking, and, in addition, it is not allowed. As to the real one danger—side-slip—the best preventive is to use "non-skids," such as the Continental armoured tyres, if the roads are greasy—anyway, this may be done until the driver has developed confidence and the instinct of how automatically to act if a skid occurs.

How to Reach Home with a Broken Mechanically Operated Inlet Valve Stem.

The easiest way of doing this is, of course, to carry a spare valve and to replace the broken with a new one. If the "spare" is not to be had the end of the damaged valve can be drilled to take a thin nail, which will make the valve stem once more of the correct length, so that when the valve is home on its seat the head of the nail almost touches the top of the valve tappet. The nail can be made secure in the remains of the valve stem by driving in a very thin French nail so as to key it in position. If a nail is not procurable, though most motorists carry such things, having, as a rule, found them in their tyres, then by cutting off some turns of the inlet valve spring so as to make it weaker, the stump of the valve stem can be passed through the spring. A washer can be slipped on and held in place by a nut, which can roughly be forced on to the end of the stem and fixed by burring the stem over it. Of course, a better job is to screw thread the tip of the stem. The mechanically operated valve is thus reduced to becoming an automatic valve, and providing the spring is sufficiently weak it will work as one.

Argyll Cars.

Messrs. Argylls, Limited, have just issued a new catalogue of their cars. Some particulars of their automobiles were given in THE LANCET of May 30th, 1908, and it will be noticed that the 14–16 h.p. model is now provided with dual ignition, having high-tension magneto in addition to the accumulator and coil method of exploding the mixture, which until now was the only one fitted. The price, too, has been reduced, while a complete and efficient set of tools and "spares" is supplied with every car. The company have been completely reorganised, and in addition to the 14–16 h.p. model they are especially drawing attention to an entirely new model, a four-cylinder 12–14 h.p., which is designed on the unit system and is well suited to fulfil the requirements of the medical motorist. Fitted with a two-seated body, it appears very good value for the price asked—£275—and for an additional £10 it is supplied with a standard side entrance body. The "over-all" length is 11 feet 2 inches, which is also an advantage for a medical man, as this permits of easy turning. The catalogue, in addition to giving particulars of the various models, has some excellent line drawings of the leading components of the chassis. It can be had on application at Argylls, Limited, Alexandria by Glasgow, or from their London Depôt, 6, Great Marlborough-street, W.

On the Cost of Running a 14–16 h.p. Argyll Car.

Dr. J. R. Holmes of Bostal Hill, Plumstead, writes: "I bought a 14–16 h.p. Argyll car fitted with a standard side-entrance body in May, 1907. I unfortunately did not have a speedometer fitted, so I am unable to give the actual distance run, but I have done about 1500 miles touring a year, and, in addition, have had the car out nearly every day for my medical work. Excluding tyres, the only repairs and stoppages I have had are as follows: Block in petrol-pipe, due to some foreign body; hind bolt, holding radius rod in bracket, dropping out. Neither of these delays occupied more than ten minutes. I have occasionally had the car overhauled by my chauffeur, and the following replacements were on some of these occasions carried out: New balls fitted in ball race near brake drum on back axle, three were broken; new guide to one exhaust valve, to replace one which had worn; new bearings to through shaft in gear-box; new bush to differential; new water circulating pump. About £18 would more than cover the cost of these replacements. The cost for tyres was at first heavy, as they were 810 × 90, and rather small for the weight of the car; 815 × 105 non-skidded last for about nine months on the rear wheels; of course the front ones, which are of the round tread kind, run for much longer. The car averages about 18–20 miles to the gallon of petrol. I consider the car now, after two years' running, to be in very good condition; in fact, quite recently she gained the hill-climbing prize at the Brooklands Meet of the Blackheath Automobile Club."

Publications Received.

From the point of view of the medical motorist there is much general information in "The Chauffeur's Companion," by "A 4-inch Driver" (Messrs. Mills and Boon, Limited), and the volume is bound to interest and be of use. The author starts with a brief and very clear description of the internal combustion engine, and the method of conveying the power obtained from it to the road wheels. The chapters on management, driving, and road stops should certainly help to make the reader one of those lucky individuals, and some really exist, for whom any old car will go. Some of the advice to prospective buyers who order a special body is worth the consideration of the profession, especially as so many doctors order a special body. "Specify everything. Body builders are simply ruinous for extras, and they will charge you any price they think fit if you do not tie them down very tightly. Make the builder keep the body low and have the boards of the seats (not the cushions), especially the back ones, built two inches higher in front than at the back." The writer knows from experience that the difference in comfort is extraordinary.

THE ANNUAL REPORT OF THE GENERAL BOARD OF COMMISSIONERS IN LUNACY IN SCOTLAND.[1]

DURING the year 1908 there was, in the jurisdiction of the Commissioners in Lunacy for Scotland, an increase of 267 in the number of registered lunatics, 223 of these being pauper patients and 44 being private patients. Since 1858 the number of lunatics on the register of the Board has increased 206 per cent., while the increase of population during the same period has been 59 per cent. The total number of private patients rose slowly but steadily for many years, but from 1898 to 1903 the proportion remained unaltered, and since then the numbers have fluctuated slightly, but have shown no real increase. The proportion among pauper patients increased steadily up to 1905, after which the rate of increase either fell or proceeded slowly. In 1902 the number of both classes of patients added to the register amounted to 3669. That number has never since been attained, and was markedly less in the years 1905, 1906, and 1908. A decrease of 105 took place in the last year, as compared with the previous year, which but for a decreased rate of removal from the register by discharge and death must have resulted in a decrease of the total number on the register, notwithstanding the increase of population of the country generally. From 1874 to 1883 an average annual increase of 40·4 persons per 100,000 registered as lunatics occurred, and from 1884 to 1893 the average increase was 41·3. In the succeeding ten years a marked rise took place, the average proportion for that period per 100,000 being 49·2. This period, from 1893 onwards, appears to have coincided with the extensive development of the hospital side of asylums, but this influence appears now to have reached its greatest strength, as during the last five years the average has fallen to 47·7. It would therefore seem that there is a decrease of occurring insanity in forms calling for certification.

The proportion of recoveries among private patients has varied from year to year, but it has shown no certain indications of falling off. Among pauper patients a continuous decrease is recorded between 1880 and 1904, and in the past four years a tendency towards a still further decrease seems to have obtained. It appears that the recovery rates have in recent years been unfavourably affected by the increased use of observation wards connected with the parochial hospitals of several large parishes. These wards receive persons suffering from passing attacks of mental disorder, of whom some, in the absence of such wards, would have been removed to asylums, and would have been discharged recovered shortly after admission. The lowering of the rate is also to be ascribed to the accumulation of chronic patients and to the fact that improved nursing and hospital care have led to the use of asylums for the reception of patients whose age and mental and physical condition are such as to preclude hope of recovery. So far as the death-rate is concerned, there does not seem to be any material change from the rate of preceding years.

The report contains an exceedingly interesting account of the attitude of the Board towards those whom it terms "mentally affected boarders under private care who are not certified." The attitude is so enlightened that it deserves very special attention from the profession at large, and we would also venture to say from the English Board of Commissioners. In England no provision is made for those who are mentally affected but whom it would be mischievous, or absurd, or both mischievous and absurd, to certify. Such a patient cannot be received by those who alone are competent to look after him and assist his cure, but must perforce be certified or kept amidst those home surroundings which are notoriously inimical to his welfare. In Scotland, where a visit from a Commissioner is not regarded by the visitor and the visited as a domiciliary police inquisition, the Board requires the names of uncertified boarders in the houses specially licensed by it to be reported, and if an interview is thought desirable such persons are seen by the Board's medical visitors, who satisfy themselves that certification is not called for. We would draw the attention of our readers to the fact that it is to the medical visitors that this duty is very properly entrusted. The necessity for the sanction of the Board to the residence under private care of mentally affected persons and its right to interfere and to have official knowledge are statutorily limited to the cases of such persons as are found to be insane or whose estates have been placed under the control of the Law Courts owing to their inability to manage their own affairs. Its sanction is not required in the case of patients whose insanity is not confirmed and who have been placed under private care for a period which cannot exceed six months upon a special certificate, nor is there any statutory obligation that it should have knowledge of them. The power of the Board to interfere in such cases would destroy the object of the provision, which the Board regards as an excellent feature of the Scottish law. It does for the wealthier class what is done in the poorer class by those large parishes which have established observation wards for a similar kind of patient. Persons affected with some mental peculiarity not amounting to certifiable insanity but yet rendering supervision necessary are frequently the cause of great domestic distress. They are neither fitted for asylum life nor for home life, and if no means existed for having them suitably supervised and cared for the position of families having such members would be an extremely sad one. In England we would point out there is no such provision, and where hardship is not inflicted it is because the provisions of the law are regarded as antiquated and impracticable, and are therefore disregarded. According to the report, persons willing to receive such boarders, and to afford them the necessary protection and care, fulfil a most useful function and ought not to be interfered with so long as no abuses arise. Many such guardians come within the Board's jurisdiction, but it is further more or less unofficially known to the Commissioners that there are others—such as medical men, ladies, and nurses—not holding their special licence who are willing to receive boarders of this class. Some of these are well known to the Commissioners and invite inspection by the Board's visiting officers. The Board has no special means of ensuring that it shall have a knowledge of all such persons, but it has reason to think that the majority is known to it, and instances have been extremely rare in which any interference has been called for. As a rule, such guardians do not look upon the Board as a body viewing their occupation inimically. They are in consequence open with the Board, and in cases of doubt or difficulty readily consult with the Board's officers, with whom relations are thus established affording the best guarantee against abuses.

It is sometimes contended that the influence which may be exerted by insane boarders upon the children and adult members of a household may be an unfortunate one. One of the Scotch Commissioners after many years' wide experience can only recall four or five instances of insanity appearing in the families of unrelated guardians, and its occurrence in these few instances was rather due to other causes than to the presence of the insane in the house. The same Commissioner speaks in terms of commendation of the efforts of the parish of Ruthven to provide for its patients under private care. Another Commissioner describes interesting cases of improvement in the mental state of patients in private houses arising from circumstances which could only occur under that mode of care. It is interesting to note that the lunatic wards of poorhouses are inspected by the Board, and on the whole the impression derived from the report thereon is a favourable one.

---

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of London.—Dr. William Collingridge begins his ninth annual report in a retrospective and comparative vein, and he takes us back 60 years, to a time when Sir John Simon, the first medical officer of the City, was calling attention in his graphic and forcible style to the need for a better water-supply in these words. "In the City of London the supply of water is a fraction of what it should be. Thousands of the population have no supply of it to the houses where they dwell. For their possession of the first necessity of social life such persons wholly depend on their power of attending at some fixed hour of the day, pail in hand, beside the nearest stop-cock, where, with their neighbours, they wait their turn—sometimes not without a struggle—during the tedious dribbling of a single small pipe." And Dr. Collingridge might, if he wished to do so, describe the gradual sweeping away of the shallow wells, the progress and disestablishment of the old water companies, the creation of the Metropolitan Water Board, and, curiously enough, the sinking of private wells right down into the chalk of the London basin, for no other reason than that it was found cheaper to do this than pay the charges of the Water Board. Dr. Collingridge states that a considerable number of artesian wells have recently been sunk in the City, and that more are in contemplation; the water yields on analysis excellent results. Sir John Simon's description of the housing conditions in the City only 60 years ago seems to us in these days little short of appalling "It is no uncommon thing in a room 12 feet square or less to find three or four families *styed* together (perhaps with infectious diseases among them), filling the same space night and day—men, women, and children in the promiscuous intimacy of cattle." The night population of the City in 1901 was 26,923, but there was no day census taken at that time, and Dr. Collingridge is hoping that there will not be a similar omission in 1911, since he rightly regards it as essential that the number of persons for whose well-being during their working hours the Corporation takes such an active interest should be officially ascertained. It may be added that the cost of taking the last day census was £1350. There was in the summer of last year an outbreak of illness in a large business establishment which was traced to the use of a much advertised rat poison which was said to cause a fatal contagious disease among rodents, but to be harmless to domestic animals and human beings. Only such persons were attacked with vomiting, diarrhœa, and cramp as had dined in a certain room under the floor of which a large number of decomposing mice were found, the mice having been killed by the use of the virus in question. It was apparently concluded that the mice carried the poison about on their feet and thus infected the furniture, plates, and other articles in the dining-room. Dr. Klein found an organism in the stools of the patients which was identical with that found in the virus. With the view of encouraging the process of cremation the Corporation has, at Dr. Collingridge's suggestion, reduced the charges for cremation at Ilford. This method of disposing expeditiously of human bodies finds little favour with the less educated classes and it is an interesting fact that if the list of those who have undergone cremation be examined it will be found how largely the names of well-known persons predominate. The explanation is probably to be found in the fact that to make the necessary anticipatory arrangements for the performance of this ceremony requires more philosophy than is [illegible] As the secretary of [illegible] rves, "Cremation in [illegible] to persons of some intellectual distinction. The average citizen is still held in the bondage of custom in which sentiment has taken root so deeply as to make it hard to eradicate." At the instance of the Corporation, in conjunction with the Chamber of Com- [illegible] was made by three [illegible] or R. T. Hewlett, [illegible] by Dr. Collingridge [illegible] The results in many [illegible] the investigators, two of wl [illegible] reported [illegible] not steril [illegible] Dr. Collingridge made praiseworthy efforts to bring about the marking of New Zealand tinned foods in such a manner as to indicate when and where they were packed, and it is much to be hoped that he will be as successful in his efforts as he has been in dealing with the soda-water industry in the [illegible] report as to meat-supplies during 1908.

The City of Birmingham.—The general death-rate of this city, with its estimated population of 558,357, was for 1908 only 15·9 per 1000, which is the lowest death-rate ever recorded, the corresponding rates for Glasgow being 17·7, Liverpool 19 2, and Manchester 18·2. Dr. John Robertson gives, however, reasons for concluding that the methods adopted by the Registrar General in estimation of populations over-estimates the people of Birmingham by some 25,000 to 30,000. The central portion of the city is decreasing steadily in population, a large number of people seeking [illegible] being more wholesor [illegible] too, it is cheaper. [illegible] ge is that a large number of people, who during the day earn their livelihood under the protection of Birmingham corporation reside in districts beyond its operations, and Dr. Robertson foresees, if the present drift continues, as it assuredly will, a condition of affairs not unlike that of London, where there is, he says, much overlapping of authorities. He trusts that some means will be found to prevent a similar occurrence in Birmingham. In his opinion there is a well-defined area for a town such as Birmingham, and he suggests that a radius of five miles from the centre of the town might, now that the means of communication have so greatly improved, be taken as a convenient limit. Possibly Dr. Robertson is contemplating a scheme which would extend the city limits to this limit, and if so, and if this extension is allowed, there will soon be a very great increase of the population of what will then be called Birmingham. But Parliament seems somewhat shy of these great extensions, as was shown in the case of Liverpool when she sought to swallow up Bootle. But Parliament and ideas are apt to change. To turn, however, to less debateable points, there is much of interest in the report before us, and the figures relative to [illegible] instructive. Of the cases admitted [illegible] of scarlet fever 145, or [illegible] not to be suffering from this disease, and it seems that of these 145 cases no fewer than 45 contracted the disease, of whom 18 per cent. died. This is a sufficiently serious matter, and it raises questions as to whether there should not be diagnosis at home before removal by a recognised expert. The large number of erroneous diagnoses in 1908 seems to have been in great measure due to an epidemic of German measles. In the case of diphtheria 44 out of 510 admissions were wrongly diagnosed, but fortunately none of them contracted diphtheria in hospital—a fact which may be partly explained by the lower infectivity of the disease and partly by the fact that each patient certified to be suffering from diphtheria is placed in a separate ward until the diagnosis is confirmed or negatived. Apparently this is not so with patients certified to be suffering from scarlet fever, and such isolation accommodation would have to be upon a very large scale. But omission to provide a large number of small wards is certainly the strongest criticism which can be directed against isolation hospitals generally, although the cost of their provision in adequate numbers would be almost prohibitive. However, there is a reasonable mean in all these cases. As regards the antitoxin treatment of diphtheria, it appears that it is not resorted to as much in the poorer as in the better circumstanced districts in spite of the fact that the University provides supplies of antitoxin.

4. In the scheme the county system has been adopted, because it is the system upon which the Territorial Force is organised, and which the British Red Cross Society has adopted as the basis of its constitution.

5. The County Association therefore is charged with the responsibility of the organisation of voluntary aid in the country.

6. Each County Association should through the medium of the local branches of the British Red Cross Society form " voluntary aid detachments," with an establishment which is laid down in the scheme; also each county group of voluntary aid detachments (and there need be no limit to the number of such detachments), should be under the command of a County Director, and each detachment should be capable of being used either as a clearing hospital, or as a rest station, or as an ambulance train *personnel*, as the circumstances of the moment may demand in the time of war.

7. Each voluntary aid detachment should therefore be trained in such a manner as will enable it to perform any one of these functions.

8. The training and equipment of voluntary aid detachments will be carried out in whatever way the British Red Cross Society may think fit; but they should be so arranged as to enable the detachments to make use of local resources [illegible] -tion and transport of wounded, and fo [illegible] care and treatment until they reach the [illegible] chments would therefore be specially [illegible] ded, and women's detachments in the preparation of food and in nursing duties.

The *personnel* recommended for each Voluntary Aid Detachment is as follows:—A. Men's Division (British Red Cross Society): 1 commandant and 1 assistant-commandant (if possible these are to be officers with military medical training); 2 medical officers; 1 quartermaster and 1 assistant-quartermaster; 2 pharmacists and 2 assistant-pharmacists; 4 under officers and 48 men. B. Women's Division: 1 commandant and 1 assistant-commandant (these being medical officers); 1 quartermaster and 1 assistant-quartermaster; 2 lady superintendents and 20 women, of whom 2 shall be fully trained nurses. This establishment allows of the divison of the whole detachment into two completely organised halves.

9. In order to obtain some uniformity in the standard of efficiency of voluntary aid detachments there will be annual or other inspections by military authorities, and a return of the members of each detachment will be submitted through the county associations to general officers commanding-in-chief periodically by each county director of voluntary aid detachments.

10. In time of war the evacuation of sick and wounded of the Territorial Forces will be under the direction of officers of the Royal Army Medical Corps or other officers appointed for the purpose, and voluntary aid detachments will be placed at their disposal and under their orders according to requirements.

11. If county associations fail to obtain an organisation of voluntary aid detachments to fill the gaps in the medical service between field ambulances and general hospitals they must report the facts to general officers commanding-in-chief.

12. As regards general hospitals, county associations should either themselves or through the British Red Cross Society proceed to select the necessary buildings in consultation with administrative medical officers, officers commanding the general hospitals, and sanitary officers of their territorial division; and plans should be drawn up showing how the buildings will be arranged for hospital purposes; the organising matron also being consulted regarding these.

13. Schedules of equipment for general hospitals are drawn up in the scheme as a guide. County associations should delegate to the British Red Cross Society the duty of providing the equipment and should satisfy themselves that it will be ready on mobilisation.

14. Supplementary personnel required for general hospitals should be obtained from voluntary aid detachments which will be allotted on mobilisation for this purpose only.

15. Wounded may accumulate in excess of the number of beds vacant in the general hospitals. The formation of convalescent homes and depôts and provision for expansion of the general hospitals must therefore be contemplated. County associations should be responsible for taking the initiative in asking the British Red Cross Society to submit schemes in time of peace for forming convalescent homes and auxiliary hospitals.

Full details of the scheme follow this outline, and three appendices describe (1) the organisation of the medical service of the Army; (2) the organisation and resources of the Red Cross Society of Japan (a report by Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C.); and (3) the detailed equipment of military hospitals (comprising schedules of all furniture, utensils, medicines, and stores).

ROYAL NAVY MEDICAL SERVICE.

The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet:—Thomas Brown Shaw, Alfred Thomas Gailleton, George Sandys Davidge, and Percival Thomas Nicholls (dated August 10th, 1909).

The following appointments are notified:—Fleet-Surgeons: F. W. Parker to Portland Hospital, and P. E. Maitland to the *Albion*, on recommissioning. Staff-Surgeon: J. O'Hea to the *Victory*, additional, for disposal. Surgeons: L. C. Rowan-Robinson to the *Drake*; S. H. Vickery to the *Impregnable*; and W. Mearns to the *Actaeon*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. J. S. Simpson, C.M.G., has been appointed to the Eastern Command for duty. Lieutenant-Colonel A. T. I. Lilly and Major J. Thomson have been instructed to prepare for embarkation for India.

INDIAN MEDICAL SERVICE.

The promotion of Major Asher Leventon is antedated to Jan. 29th, 1907. The promotion of Major Jasper Maxwell Woolley is antedated to July 29th, 1908.

The King has approved of the following promotions:—Lieutenants to be Captains: Arthur Falconer Hayden (provisionally) (dated Sept. 1st, 1908); Percy Strickland Mills (provisionally) and Frank Phillips Wernicke (dated Feb. 1st, 1909); and Charles Richard O'Brien, Norman Haliburton Hume, Greer Edmund Malcolmson, and Duncan Macdonald Cochrane Church (dated March 1st, 1909).

Major F. D. Browne has been appointed to the substantive medical charge of the 112th Infantry, Kohat; and Captain A. S. M. Peebles is appointed to the substantive medical charge of the 18th Lancers, *vice* Captain R. F. Baird.

ROYAL VICTORIAN ORDER.

The King has appointed Fleet-Surgeon Cyril James Mansfield, R.N., H.M.S. *Indomitable*, to be a Member of the Fourth Class of the Royal Victorian Order.

DEATHS IN THE SERVICES.

Brigade Surgeon-Lieutenant-Colonel Edwin James Fairland, A.M.S. (retired), on August 6th, at Bournemouth, aged 65. He entered the service in 1867 as assistant-surgeon, was promoted surgeon in 1873, surgeon-major in 1879, surgeon-lieutenant-colonel in 1887, and brigade surgeon-lieutenant-colonel in 1893. He served in the Abyssinian campaign from November, 1867, to July, 1868 (medal). He retired in 1897.

THE TERRITORIAL ARMY IN WAR.

In an interesting article on "The Health of the Territorial Army in War," in the *Broad Arrow* of August 14th, Lieutenant-Colonel W. Hill Climo, A.M.S. (retired), said that it is an unjustifiable assumption "that, as the Territorial Army will not be serving outside the United Kingdom, it will not be exposed to conditions inimical to health either in regard to its endurance or to environment and climate. Some such optimistic opinions were held about the Boer War, and we know with what disastrous results, though probably the climate of South Africa is the most favourable in the world for the conduct of a campaign, and though no army ever before was so lavishly provided with food and other supplies. An army, organised as the Territorial Army is, if mobilised for service in the Garden of Eden, would, under service conditions, be liable to dysentery and enteric fever. In England it would be impossible to bring 10,000 troops together free from the seeds of enteric fever, which under the stress of war would become epidemic. The best medical service in the world could not prevent its occurrence with unseasoned and immature troops. Voluntary service armies are notoriously the most unhealthy, and the Anglo-Saxon race is perhaps the most susceptible to these epidemic diseases, the brunt of which falls on the intestinal tract."

Correspondence.

THE DANGERS OF CARBON TETRA-CHLORIDE.

To the Editor of THE LANCET.

SIR,—I have read with much interest the article published in your issue of August 7th on the toxicity of carbon tetrachloride. Three cases in which ill effects have followed the use of a dry shampoo have recently come to my notice. In the first case, a girl, aged 22 years, became, according to her own statement, "completely unconscious" whilst her hair was being treated with a patent non-inflammable dry shampoo. Under the same treatment at the same hairdresser's a second lady, aged 26 years, became "deafer and deafer" until she was obliged to ask the operator to desist, fearing that she was going to faint. At another establishment a lady, aged 40 years, became so faint during the application of a dry shampoo that the process had to be stopped. All the windows in the room were thrown wide open, and at the end of half an hour the lady had sufficiently recovered to have her hair hastily dressed. Still feeling very faint and shaken, she was then driven straight to her home in a cab. These three cases occurred before the recent fatal case, and I have hesitated to publish them because although the histories came to me at *first hand they were not given me in my professional* [illegible] investigated. The patients [illegible] certainly free from cardiac [illegible]

I am astonished to learn that in spite of the recent fatality the use of this shampoo continues unchecked, the public being apparently lulled into a sense of security by the medical evidence, which stated that the lady who died suffered from heart disease. The hairdressers justify themselves by stating that although untoward symptoms occur amongst their customers the operators have never been known to have been affected. Their immunity is fully explained by the weight of the vapour of tetrachloride of carbon, which, according to Dr. Veley, is five times that of air. Unless my experience has been exceptional, there should be abundant clinical evidence in support of the views as to the dangers of tetrachloride of carbon which Dr. A. Waller and Dr. Veley base on laboratory experiment, and the use by hairdressers of shampoos containing so poisonous a substance should certainly be prohibited.

I am, Sir, yours faithfully,
August 16th, 1909. J. E. SANDILANDS, M.D. Camb.

THE NATURE OF ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—May I trespass on your space to urge once more the desirability of the abolition of the terms "false" angina pectoris, "pseudo" angina pectoris, and the like. In an [illegible] I [illegible]ntributed to THE LANCET [illegible] "angina cordis" might [illegible] of cardiac perturbation. The term angina cordis, moreover, expresses more or less exactly the condition of the heart in these attacks and it can be suitably qualified in accordance with its mode of origin, as, for instance, angina cordis vaso-motoria, angina cordis toxicata, &c. The adoption of this nomenclature would not only get rid of the misnomer and consequent nosological confusion involved in the use of the term "false" angina pectoris, &c., but would also promote much greater precision [illegible] of several hitherto ill- [illegible] Sir T. Clifford Allbutt's [illegible]ion of angina pectoris. As Sir R. Douglas Powell points out, it is hardly possible that aortic stretching can be the only cause of angina pectoris, nor, in my opinion, is it adequate to explain all the symptoms of the anginal attack. Furthermore, the large majority of the conditions that unquestionably give rise to aortic stress are not associated with anginal symptoms; and, on the other hand, true anginal attacks are not very uncommon, in my limited experience, without any evidence, either clinical or pathological, of aortic stretching.

I have urged the importance of the localised patchy distribution of the degenerative changes that may be found in the cardiac wall in cases of angina pectoris, since in the distension and stretching of these diseased areas during the cardiac systole I find an explanation of the phenomena of the anginal syndrome. For a full exposition of this hypothesis I must, out of consideration for your space, refer your readers to my article, but I should like to point out that a satisfactory explanation of the pathogenesis of angina pectoris must account not only for the dolor pectoris but also for the angor animi. I am, Sir, yours faithfully,

London, W., August 14th, 1909. E. H. COLBECK.

To the Editor of THE LANCET.

SIR,—The few remarks which I propose to make on this important question are the result of my clinical experience of a very large number of cases of heart disease. I find that true angina pectoris major (I confine my attention to this) is [illegible] [p]oorer classes, and [illegible] hospital cases of [illegible] th three cases of angina pectoris; on the other hand, amongst the well-to-do classes of [illegible] [f]requently, and especially [illegible] The hypothesis which I [illegible] true "angina pectoris is due to spasm or cramp of the heart muscle, which comes on suddenly after exertion as a rule, and passes off as it came."

I cannot here discuss the various theories which have been advanced by great authorities as to the cause of the symptoms which are so distressing and often fatal, but I will confine my remarks to one or two points. It has been said that angina pectoris is due to sudden dilatation of the auricles or ventricles, either in association with valvular disease or often severe heart strain. My cli[illegible] does not support that vie[illegible] after a severe and punishi[illegible] during a football match, become "winded." The heart has become over-distended and they suffer from acute dyspnœa, but there is no pain and compensation is soon restored. I have never seen the symptoms of angina pectoris occur in a heart with broken compensation, and I thoroughly agree with Sir Clifford Allbutt when he says that the aorta is chiefly associated with these distressing symptoms. Three cases which I have noticed in hospital were of a very severe type and all terminated fatally, but, strange to say, none of the cases died during an attack or even near an attack of angina pectoris. Two of them occurred regularly after an excess of food, the third one developed angina occasionally after smoking strong tobacco. I kept very careful notes of the clinical course and also of the necropsies of these three patients. In the first case the heart was enlarged, weighing 12½ ounces, there was hypertrophy of the left [illegible] aortic valves, and marked [illegible] whole extent. None of t[illegible] tended, and *the left side of the heart was quite empty.* In Case No. 2 the heart was slightly enlarged with hypertrophy of the left ventricle and some aortic incompetence. In this case also the aorta showed atheroma. The heart itself was in a state of firm contraction. The coronary arteries in both these cases were patent and there was very little evidence of *arterial degeneration. In the third case, where the attacks* were induced by smoking, the heart was to all appearances quite healthy and the man died from advanced kidney disease.

To look at the other side of the picture, I have made necropsies on some hundreds of cases of heart disease in all its *forms,* including *aneurysm* and *intra-thoracic* growths, and I am sure that it is the experience of all of us that it is common to see all the various lesions and degenerations associated with the heart without the slightest sign during life of angina pectoris, so that we cannot say *that diseases of the valves of the heart or of the aorta alone* are the cause of angina. There seems to be some affinity or relation between gout, especially the gouty heart, and angina pectoris, and as it is rare to see acute gout in the female so it is rare to see angina pectoris; in fact, I have not met with a true case in the female. Then with regard to its neuralgic character, although the pain is severe and excruciating, extending, as Head has said, into various nervous areas, still the character of the pain cannot be said to coincide with neuralgia. The sudden onset, short duration, and rapid cessation are quite opposed to neuralgia and yet would correspond with spasm or cramp of the heart muscle. It is well known that gouty people are very prone to attacks of cramp, and it is quite feasible to suppose that the heart muscle may be subject to cramp also, and that the administration of any drug which produces dilatation of the arteries may also relieve muscular spasm.

Another point to consider is the extraordinary feeling which the patient suffers of impending death. In many cases, however, this feeling is due to fright caused by the intense pain. Patients have told me that the very thought of the possibility of an attack would produce the same kind of fear, and such patients live in constant dread of an attack. I have recently had under my care a gentleman of highly gouty tendencies who has been subject to attacks of angina pectoris for over 25 years. He had aortic disease following rheumatism, and *although* the pain towards the end of his life was just as acute, yet he told me that the fear and dread

---

[1] Angina Pectoris, a Criticism and a Hypothesis, THE LANCET, March 21st, 1903, p. 793.

of death had entirely disappeared because, as he said, he knew he would get relief from his nitro-glycerine or nitrite of amyl. I am quite aware that my contribution to this debate is of very little value, because I cannot reconcile the symptoms produced by angina pectoris with those found during life and after death, and I have come to the conclusion after a long observation of hospital cases that angina pectoris is much more *common* amongst the rich than amongst the poor; that it is associated as a rule with gout; and that it is caused by spasm of the muscular structures of the heart, which is immediately relieved by some vaso-dilator.

I am, Sir, yours faithfully,

NATHAN RAW.

Liverpool, August 16th, 1909.

THE MODERN TREATMENT OF TUBERCULOUS JOINTS.

To the Editor of THE LANCET.

SIR,—In opening the discussion on the modern treatment of tuberculous joints at the recent meeting of the British Medical Association I am reported in THE LANCET to have said: "Bier's congestive method was sometimes useful, but occasionally the results had been disastrous." I stated that disaster had followed the *exclusive* use of tuberculin and of Bier's congestive method, and that they should be used as mere allies to other recognised methods. I am further reported as saying that I favoured the reduction of spinal deformity at whatever stage the disease. I stated precisely the contrary.

I am, Sir, yours faithfully,

ROBERT JONES.

Liverpool, August 16th, 1909.

AN OPERATION FOR THE TOTAL EXCISION OF TONSILS.

To the Editor of THE LANCET.

SIR,—I read with much interest in your last week's issue the letter from your correspondent, Mr. H. B. Mylvaganam, recording the successful performance of the operation of complete tonsillectomy in 300 cases. He does me the honour of associating my method of procedure with his own—"there is practically very little difference in the technique adopted by Mr. Waugh and myself"—and then devotes the rest of his article to repudiating those principles which I regard as essential to my operation and which render it a simple, rapid, and bloodless procedure. I feel, therefore, that I should be doing him an injustice if I accepted the proffered compliment.

He writes as follows: 1. "In operations on the throat and nose the anæsthetic is not pushed to the same extent as required for operations on other parts of the body." 2. "Having partially anæsthetised the patient the head is allowed *to hang well over the edge of the table.*" 3. "It is not absolutely necessary to define the capsule of the tonsil. If any pieces are left behind they can be felt by the finger and removed by the scissors or by the punch forceps." He then continues: "One drawback to this method of removing the tonsils is the hæmorrhage which follows in some cases. It often struck me that the amount of hæmorrage was out of proportion to the quantity of tonsillar tissue removed." Therein I agree with him, only I regard the hæmorrhage as the direct outcome of his procedure which I have detailed above in his own words. It is clear that the amount of hæmorrhage in any operation must depend partially upon the ease with which vessels severed at the site of the operation can retract and contract, and partially upon the avoidance of any procedure which tends to produce local engorgement of the vessels during the operation. By defining the capsule of the tonsil at the first incision the rest of the operation is conducted in the line of cleavage between the capsule and the pharyngeal wall, so that the severed tonsillar vessels can retract immediately into the muscular wall. Consequently, as my experience has shown me, the cessation of hæmorrhage is spontaneous and rapid. I have therefore never used any hæmostatics, not even "hot sponges on holders," nor are there any "pieces left, which can be felt by the finger and subsequently be removed by scissors or punch forceps."

Local engorgement of the blood-vessels of the head and neck can be brought about in two ways—i.e., by the effect of gravity upon the venous circulation, and by the performance of the normal physiological acts of swallowing and coughing. At the end of ordinary expiration there is an accumulation of blood in the extra-thoracic veins. If expiration is prolonged to such an extent as to culminate in the explosive act of coughing the venous engorgement becomes excessive and consequently the flow of blood from torn veins will be free and copious. By the position in which I place my patients on the operating table with merely a sandbag under the shoulders I avoid the effects of gravity upon the venous circulation and at the same time there is a sufficient slope of the pharynx to enable the blood to trickle towards the roof of the naso-pharynx. By the employment of a brief deep anæsthesia coughing and swallowing are prevented. Consequently my operation is strikingly free from hæmorrhage and the position of the patient gives me a view of the field of operation sufficient to remove the whole tonsil. I need no better view.

Mr. Mylvaganam reassures me that he was completely unaware of my method until he read of it in THE LANCET, and whilst he is courteous enough to associate our methods as being similar I must own, that I should have hesitated to do so if he had not suggested it. With regard to the use of the conchatome as a retractor, I must express my indebtedness to Mr. Steward of Guy's Hospital for bringing it to my notice for the purpose of punching out tonsils. I found that when used in that way it soon became blunted, and that then it held tonsils firmly without tearing them. My original paper, which was written nearly a year ago, includes the cases which I had operated on continuously since August, 1906. Since then I have performed the operation on more than 1500 cases, and I still have no untoward events to record.

I am, Sir, yours faithfully,

GEORGE E. WAUGH,
Surgeon to Out-patients, the Children's Hospital,
Great Ormond-street, W.C.

Welbeck-street, W., August 18th, 1909.

A CORONER'S COURTESY.

To the Editor of THE LANCET.

SIR,—Enclosed is a reply I received from the coroner for the county of Anglesea, to a letter of mine reporting a case of sudden death. The man was dead before I arrived at the house. The deceased had never been attended by any medical man.—I am, Sir, yours faithfully,

R. ARTHUR JONES.

Bod Idris, Menai Bridge, August 4th, 1909.

[ENCLOSURE.]

High St., Bangor, N. Wales.

CORONERSHIP.

DEAR SIR,—I am in receipt of your letter stating that a man aged 66 died at Orsedd, Garnedd Goch, last night and that you never attended him, but that you were the Medical Attendant of his brother [illegible] he came to his death.

[illegible] of people in Anglesey dying without [illegible] in no way concern me.

Why, therefore, you send me a note to that effect only I cannot understand as I presume there are hundreds of people dying in Anglesey without your ever attending them, and which, as I have said, in no way concern me as Coroner.

Yours truly

R. JONES ROBERTS.

*** Mr. R. Arthur Jones here went out of his way to give Mr. R. Jones Roberts early notice of the occurrence of a death in his district with regard to which it would be the duty of any coroner to make immediate inquiry in order to ascertain whether it might be a case for an inquest or not. There seems to have been no medical man in attendance on the deceased, but Mr. Jones saw the body very shortly after death, though not before death took place. It was not, then, the duty of Mr. Jones to inform the coroner of the death, in the sense that there was no legal obligation upon him to do so. Had he not done so the coroner would probably have received through some other channel an intimation later that it had taken place. It was just a courteous act on Mr. Jones's part, and possibly also one prompted by a desire to assist the relatives, and to let the coroner know that there was a case for his attention. In these circumstances comment on the coroner's letter is not required: it condemns itself. Fortunately, these cases are rare, and it is to be hoped that the much-needed amendment of the Coroners Act will supply rules of procedure calculated to prevent such occurrences. In the present condition of the law, as we explain this week in a leading article, where no certificate of the cause of death is forthcoming, the preliminary stages which lead up to an inquest or to the dispensing with one are not very clearly marked out. Inquiries have to be made and things work smoothly or not according to the relations existing between the coroners and the medical practitioners. These relations are not likely to be improved by any letter similar to that of Mr. R. Jones Roberts.—ED. L.

THE TERRITORIAL MEDICAL SERVICE.[1]

(FROM A SPECIAL CORRESPONDENT.)

IV.—THE MEDICAL EXAMINATION OF RECRUITS: THE SELECTION OF MEN FOR ACTIVE SERVICE.

THE medical examination of candidates for the Territorial Force is carried out principally by the medical officers of the units concerned. In the regular army all officers of the Royal Army Medical Corps on joining now pass through a course of instruction in recruiting duties, a procedure which is of the greatest value to the State. Medical men who have not had experience of the many slight defects or deformities which interfere with the soldier, and the advantages sometimes taken of these defects by him to avoid duty or to get his discharge by being invalided when he tires of army life, require special knowledge which can only be imparted by expert recruiting medical officers. The physical standards for recruits vary with the various arms concerned. In the regular army the minimum measurements for height and chest girth are those laid down for Infantry of the Line, Army Corps (except drivers), Royal Army Medical Corps, and Ordnance Corps (ordinary recruits). For these classes the minimum standards for men 5 feet 3 inches in height is a chest expansion of 33½ inches, provided its range of expansion is not less than 2 inches. The minimum age laid down for recruits is 18 years, but in certain units (Army Post Office Corps, certain sections of the *Royal Engineers, and Army Ordnance Corps*), and recruits enlisted to complete drafts or units proceeding abroad, the minimum age standard is fixed at 19 years. The *majority* of recruits (95 per [illegible]
estimated that most of then [illegible]
work of a mature soldier [illegible]
available statistics (1907) regarding recruits medically inspected in the United Kingdom for the regular army show that of 59,393 recruits inspected in that year, 16,906 were rejected on inspection and 607 were rejected as unfit within three months of enlistment, giving a total for rejections of 17,513 and ratios of rejections per 1000 inspected of 284·65, 10·22, and 294·87 respectively. The figures for the decade 1897 to 1906 are even higher. The most common causes of rejection per 1000 inspected in 1907 were: (*a*) under chest measurement, 49·72; (*b*) teeth, 48·17; (*c*) heart, 29·25; (*d*) vision, 24·06; (*e*) defects of lower extremities from fracture, contraction, luxation, &c., 17·04; (*f*) varicocele, 11·42; and (*g*) under height, 10·49. The chief defects causing discharge from the service within three months of enlistment for the same period per 1000 inspected were: (*a*) heart, 1·73; (*b*) nervous system, 0·93; (*c*) weakness of intellect, 0·86; (*d*) defects of lower extremities from fracture, contraction, luxation, &c., 0·74. These, the principal causes of rejection, are of the utmost importance to all Territorial recruiting medical officers as they indicate the deficiencies most to be looked for, and when we examine the invaliding figures of the regular army it may be noted that as regards the relative importance of the different causes of invaliding, diseases of the circulatory system hold first place. This has been attributed to various causes; in the case of valvular disease occurring within the first year of service to inefficient recruiting, and in the case of disordered action of the heart within the same period to the effects of military training. It may be mentioned that the so-called disordered action of the heart met with in the service is not necessarily always functional, but may be due to dilatation of the stomach. It is understood that investigations are being carried out on this subject by the military medical authorities. The six principal causes of invaliding from the army since 1880 have been diseases of the circulatory system, tubercle, diseases of the nervous or digestive system, rheumatism, and syphilis. A brief note on some of the principal causes of rejection or discharge may now be considered.

Diseases of the heart.—The heart is perhaps the most important organ to be examined in a candidate for enlistment. The greatest possible attention must be paid to organic lesions, also to functional affections of the heart, and men must be rejected if found suffering from any marked degrees of irregularity of cardiac action which do not tend to subside after a reasonable period of rest. The accepting of recruits with hæmic or temporary bruits, while not advisable in the regular army, should only be allowable with caution in the Territorial Force, and such recruits if passed must be warned of the dangers they risk on strenuous marches, field days, &c. The cigarette habit must not be lost sight of in its rôle as a causal factor of functional disordered action of the heart. With a view to help men to overcome the habit Territorial medical officers should advise their commanding officers to prohibit the smoking of cigarettes at certain times, when pipe-smoking would be made allowable instead.

Teeth.—Loss or decay of many teeth causes nearly 17 per cent. of the number of all rejections for the service if we exclude failure to attain the physical standard of size. The South African war caused a high standard to be laid down, but opinion is now held that the inefficiency attributed to defective teeth was then much over-rated, and that a great proportion of the dental troubles were due to scurvy from want of fresh food, meat, and vegetables, added to the prolonged duties in the field. In some cases the teeth of recruits may be brought up to the standard by dental treatment. The acceptance or rejection of a recruit on account of loss or decay of several teeth depends upon the relative positions of the sound teeth. Thus the loss of several contiguous molars on both sides interfering with efficient mastication, or, again, the loss of many teeth in a recruit of an indifferent constitution, would point to rejection. In the case of the Territorial recruit the standards laid down for the regular army as regards the teeth may be more elastic and the criterion of dental fitness should depend on the general nutrition of the candidate. Special attention should be paid, however, by Territorial medical officers to the question of pyorrhœa alveolaris which is not uncommon in young men. It is more commonly found on one side of the mouth associated with deposit of tartar and can be often remedied by application of peroxide of hydrogen. Its presence has such an important bearing on the general health that the condition should never be overlooked.

Varicocele.—This condition formerly used to be the cause of a fair number of rejections in recruiting, but latterly it is viewed with greater leniency. There is said to be a widespread belief that even a slight degree of varicocele is responsible for impotence, and the demand for operation may be attributed to this fact rather than to any pain or other trouble. But the question of varicocele is a complicated one.[2]

Flat feet.—Recruits who show by practical tests that the arches of the feet are strong may be accepted, although the feet may appear to be flat. The regulations as modified in 1907 were the means of passing about 500 men into the regular army in that year who would have been rejected under the former rules. The proof that such men became efficient soldiers is shown by the ratio for discharges under three months' service, which have since fallen.

Syphilis.—It is definitely laid down that men suffering from the constitutional form of this disease cannot be enlisted in the army. Men suffering from constitutional syphilis are extremely likely to break down under the strain of active service.

Selection of Men for Active Service.

Here the standards laid down must be much more rigorous.

---

[1] Nos. I., II., and III. were published in THE LANCET of July 31st and August 7th and 14th.

[2] See THE LANCET, Sept 23rd, 1905, p. 923, and the important correspondence which followed on Colonel Frank Howard's communication.

In the mobilisation of troops for active service in the field, especially for a tropical campaign, the selection, not alone of the individual, but also of the unit, is of such vital importance as to be what we may almost term the key to the position of success. Many factors enter into the consideration of this question, of which the following are, perhaps, the more important. As previously recorded, any regiment or other unit that has been noted for its sanitary conservancy in barrack life in peace time may be relied on to carry such an attribute with it into the more severe test of active service, and *vice versâ*. For a regiment that is careless of its hygiene in peace may of a certainty be prophesied to fall to pieces with enteric fever or other fell dirt disease in war. The question also of units home from the tropics, shattered and decimated by malarial fevers or venereal disease, will always arise, and, if the individuals debilitated by these diseases be not thoroughly eliminated by strict medical examination prior to disembarcation, they will fill the hospitals on field service and paralyse any regiment from wastage. Such regiments will be a delusion and their strength a paper one, and as they will only reflect the utmost discredit on all concerned they should never on any occasion be allowed to take the field; it is far better for the officer in medical charge of such a unit strenuously to oppose any attempt for it to do other than garrison duty at home. Its officers and men who are "fit" should get opportunity for transfer to staff or other extra-regimental appointments as volunteers for the seat of war, so that disappointment need not ensue.

Passing next to examine the individual, it is, of course, impossible to lay down hard-and-fast rules suitable for all cases, as each must be judged on its own merits.

Age.—The short-service system initiated by Field-Marshal Viscount Wolseley, as is well known, gives us a larger proportion of young soldiers in the regular army than would otherwise be the case; so there is but little age choice when it comes to mobilising a large field force, even when taking into consideration the men of the Army Reserve. Lord Wolseley's views in respect of the value of young soldiers are well known and common property; he deems young non-commissioned officers also as important an essential as young recruits. The history of Napoleon's campaigns, and those of the other great continental Powers, as well as that of our own, all give overwhelming evidence of the fact that old and seasoned troops are much the best. From personal experience, and from the closest possible attention to this subject while attached to units which were invariably employed in the fighting lines during General Buller's handling of the Natal army in the general engagements at Spion Kop, Vaal Krantz, Colenso, Pieter's Hill, relief of Ladysmith, Laing's Nek and Belfast, as well as in many other engagements of lesser importance in Natal, Orange River Colony, and the Transvaal, in which there was a fair opportunity of estimating and reflecting on the value of the influence of age on the health and efficiency of the soldier of all types, from the recruit to the seasoned soldier and reserve man, of contrasting home-bred and colonial, regulars, irregulars, yeomanry, volunteers, and militia, the writer has no hesitation in stating that, from a purely medical point of view, it is less satisfactory to select men under 25 years of age for active service. They are more liable to break down in a protracted campaign from over-strain and fatigue, and to knock under to enteric fever, dysentery, or some other disease. From a military point of view, however, it may be conceded that more initiative in times of emergency was found among men of under 25 years than among the men of more mature age, such as belonged to the army reserve; perhaps this may in some part be due to the fact that the latter, having contracted home ties and settled down from army life, have to some extent become softer in muscle and more cautious of limb. Probably if we strike a mean between the age of the recruit and that of the army reserve man we have the right material for war as British soldiers, for such men should have all the advantages of seasoning and few, if any, of the susceptibilities.

It is hardly necessary to remind our readers that experience in war, and also in peace, has taught army surgeons the bearing that age has on the susceptibility of the soldier to enteric fever, the principal bugbear. Men between the ages of 20 and 25 are by far the most susceptible to this disease, as they have not yet matured. Examples of immaturity may be found in the bones of the skeleton, many of which are not wholly united; moreover, the heart, lungs, and viscera have not matured until the individual has attained his twenty-fifth year. The present short service system robs us of seasoned soldiers; by "seasoned" men is meant the survivorship of the fittest, that is, men with their weaker comrades weeded out by the effect of tropical service, not men who have had tropical diseases, such as malarial fevers or dysentery, as such individuals are especially predisposed to further attacks on the least exposure. The majority of our recruits under the present short service system are under 20 years of age; they do not remain sufficiently long at home, and are sent abroad before they are matured. Under the new, easy-going, and attractive surroundings of a foreign station, these men, one and all, at some period of their first few years' service, contract either venereal disease, malarial fever, or enteric, or perhaps a combination of these maladies, the result being that these diseases, after eliminating the weaker individuals, leave the best educated of the remainder to be promoted to the rank of non-commissioned officers, and these in turn are discharged from the service just as they reach the age and period of seasoned soldiers. One has only to take the medical history sheets of a regiment *en bloc* and go carefully through them when the truth of these statements will be apparent. In Lord Roberts's great march from Cabul to Kandahar the effect of age and seasoning in soldiers was well brought out; all the regiments engaged marched well and improved daily, all except the 72nd; on inquiry it was found that the marching power of only a limited section of this regiment was affected, and that the companies affected were made up of newly arrived drafts of young men. In Natal the writer noticed very much the same sort of thing. During General Buller's forced marches from Ladysmith and Elandslaagte to Laing's Nek, *viâ* Helpmakaar, Dundee, and Newcastle, the Light Infantry Brigade, which acted as advanced guard to the main army, covered distances varying between 20 and 25 miles daily; the troops were all seasoned, save for drafts and volunteer companies that had come out from England, and when men fell out they were invariably found to be recent arrivals. On the other hand, the Lancashire Brigade, to which the writer was for some time attached, were second to none as a fighting unit, but were notoriously slow marchers, chiefly owing to the large number of reservists they counted in their ranks. Sir Thomas Crawford, a former director-general of the Army Medical Department, fixed the low limit of suitable age for active service at 23 years. The Army Sanitary Commission, in reference to Indian trooping, advised that no one under 25 years should be sent to India. The French Foreign Legion in Algeria is composed of only seasoned troops. These, and many other instances, all point to the fact that there can be no possible doubt that 25 is the age we must circle round, preferably over 25, as the most suitable for campaigning in the tropics.

Previous medical history and its bearing on selection for active service.—In the medical examination of the men of a regiment detailed for active service the medical history sheets of each individual must be carefully scanned while they are subject to examination. All cases with lengthy hospital admissions for venereal disease or malarial fever must be particularly gone into, and, *as a rule*, should be rejected as unfit, as the efficiency of a field force depends on the efficiency of the men composing it, and there are no diseases more prone to return or induce debility from functional disturbances of the heart and circulation than malarial or venereal affections. Cachectic and anæmic men, with past histories of malarial fever, should invariably, for this reason, be rejected, as they will break down in the first few weeks of any campaign. In the very first march the Lancashire Brigade made in South Africa, from Chieveley to Frere, a good example of this came to notice. The brigade started from Chieveley at 3 A.M., before dawn, and amid torrents of rain, over tracks covered with mud and slush; it marched until 5 P.M. in the afternoon. Most of the troops had no great coats, having left them in the waggons. The waggons of the Brigade Field Ambulance were filled to their fullest extent, the majority of the patients being reservists, in whom the quiescent germs of malaria had been called again into activity by the cold and rain. They presented a pitiable spectacle as they lay, cold and shivering, wrapped up in the Government blankets provided by regulation in [illegible] ment. All these cases had to be [illegible] ival at

Frere, and all had more or less lengthy histories of previous attacks of malarial fever; these men had only been in the country a week, and were useless as soldiers for active service. Many of them had to be invalided at once. Venereal disease is another most important factor to take into consideration while estimating the value of men for active service. Needless to state, no case of primary sore or gonorrhœa should be allowed to embark, as even for prophylaxis sake every channel of origin of any infectious disease must be eliminated from the country which troops propose to fight in. During the physical examinations as to fitness this matter will naturally have to be attended to by the medical officer. He should also form some estimate from the man's medical history sheet as to his previous admissions to hospital for venereal disease, and reject all cases of syphilitic cachexia, anæmia, and chronic orchitis, as such cases invariably break down.

Physical examination.—Having glanced over the medical history sheets to estimate the two diseases, malarial fever and venereal disease, and having eliminated entries for any other serious disease, the medical officer can pass on to the physical examination of the man himself. This examination must be as thorough as time will allow. The system the writer has adopted on occasions where he has not had the advantage of the assistance of a brother officer, and where time and the exigencies of the service did not permit of what should, perhaps, have been a more careful examination, was as follows. A company was paraded at a certain hour. The colour-sergeant of the same handed the writer a nominal roll, giving the men's names, numbers, and initials, and also their medical history sheets, arranged in the same order as they appeared on the roll. The men were marched into the room (as large a one as possible is advisable) in batches of ten; each man had nothing on but his shirt and overalls. The men were arranged in file at wide intervals. The front row took off their shirts, and as each man's turn came for examination he let fall his overalls, so that the entire body was seen in turn. Special attention was paid to the detection of discharges from ears, to blepharitis, teeth, heart, rupture, venereal disease, varicocele, varicose veins, deformities of feet, and piles. In examining for rupture each man's abdominal rings were examined, and he was made to stand on tiptoe and cough; and for condylomata and piles to stoop and touch his toes. To avoid personation the company colour-sergeant stood by, and each man was asked either his number, initial, or place of enlistment, or some other question from his medical history sheet; his power of hearing also was estimated by this question.

The degree of any of the above-mentioned defects that can be passed must lie with the individual discretion of the examining medical officer. No case of perforation of the membrana tympani ought to be sent on service; cold and exposure only aggravate it, and its danger to life will be increased. This disease is particularly common amongst the Royal Artillery, and especially the Royal Garrison Artillery; in the Royal Artillery it is usually caused by duty; in other branches of the service it is usually the result of carelessness in drying the ears after a plunge-bath or washing.

Blepharitis is an eye trouble very prone to increase and lead to conjunctivitis on service, especially in dusty or sandy tropics; if this disease is at all markedly present, or if there is absence of many eyelashes, such a soldier ought not to be allowed to go on service. The question of teeth is a more difficult one, and when on service really depends on the keenness of the individual for soldiering, for the writer has seen men in a campaign get along in perfect health with a most limited supply of teeth, and others readily go sick on the smallest excuse and proclaim their inability to eat field rations. As a rule, no man without a good bite of at least four opposing molars should be passed, and all signs of caries with suppurating fangs ought to be rejected. Too much weight need not be attached to carious incisors. The question of artificial teeth is doubtful, and the writer would be disinclined to reject a candidate if otherwise satisfactory; but we must always be suspicious of the worth of such individuals, as they have only to lose their plates to claim exemption from all duties. Non-commissioned officers, as a rule, should be passed at a lower standard as regards teeth than privates. Each and every candidate with any form of cardiac murmur must naturally be rejected at once, and the same rule will hold good in organic disease of the lungs or other viscera.

Venereal disease has already been dealt with and the rules laid down should be rigidly enforced. No case of rupture, however slight, should be passed, as the tendency to increase is always present. Rupture cases wearing trusses should also be rejected, as carrying stones for entrenchments will bring on a relapse. Mild cases of varicocele and varicose veins cannot be stopped, as such a large proportion of men have them; cases of piles, on the other hand, should not be allowed on service, as the condition will never tend to improve but rather to get worse. With regard to feet troubles, no marked cases of bunion, hammer-toe, or flat-foot should be passed, as marching is of cardinal importance, and if men have any excuse in the shape of deformity of toes they will continually fall out on the march and fill the ambulance wagons.

F[illegible] 1. I[illegible] in[illegible] individually as to fitness for field service, and that this examination be carried out in a most thorough fashion. In the Boer war many were sent out who were utterly unfit for war service. 2. The medical officer in charge of a unit in peace time and no other should invariably be detailed to accompany it in war; he will thus know the health of its officers and men, and such experience is invaluable. 3. On mobilisation the bandsmen of the regiment should be handed over entire to the medical officer for special training in first aid and sanitation.

(To be continued.)

CHOLERA, PLAGUE, AND OTHER DISEASES IN RUSSIA AND THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

[illegible]

[illegible] those furnished in [illegible] 259):—

Between June 14th and June 20th	...	664	cases,	234	deaths.
"	" 20th " " 27th	...	880	"	365	"
"	" 28th " July 4th	...	1130	"	461	"
"	July 5th " " 11th	...	858	"	384	"

(All the dates are according to the Old Style)

In the first of these four weeks the disease was confined to the towns of St. Petersburg and Riga and the governments of St. Petersburg, Archangel, and Novgorod. In the second there were added to these the governments of Vologda, Pskof, Yaroslavl, Riazan, and Olonetz. In the third, in addition to most of the governments already mentioned, cholera had appeared in those of Vilna, Courland, Livonia, Moscow, Viatka, Vitebsk, Simbirsk, and Finland. Finally, in the fourth week, the names of three governments—those of Estland, Tver, and Kostroma—and the town of Cronstadt appear for the first time in the list. By far the larger part of the totals in each week refers to the outbreak in St. Petersburg. Elsewhere only the governments of Archangel, [illegible] and Riazan have furnished a number of [illegible] *In many of* [illegible] ngle isolated [illegible] een. It will [illegible] the numbers have begun to decrease; but it would, perhaps, be premature to conclude from that that the worst of the epidemic is over. We have only now reached the season in which, in each of the last two years, the cholera epidemic in Russia has begun its ravages. The infection may yet spread to the valley of the Volga and the south of Russia, in which event considerably higher totals than those above quoted may be expected to figure in the weekly returns. [illegible] St. Petersburg [illegible] in large numbers of cholera vibrios in the water of the Neva. A Commission has been appointed by the Russian Government to deal with the question of the St. Petersburg water-supply and drainage schemes. The composition of this

Commission will be as follows: a President, appointed by the Tsar; a certain number of members, appointed by the Senate; six members named for three years by the St. Petersburg town council; two members chosen for the same period by the *zemstvo* of the St Petersburg government; and not more than four members named by the Tsar. The example of England is quoted where the cholera outbreaks that occurred between 1846 and 1860 led to the inauguration of those great public health measures and legislation which have produced such brilliant results in the last few decades of the nineteenth century.

The execution of the new scheme of water-supply in the Russian capital will require some 15 years for its completion. In the meantime, in order to deal with the existing outbreak of cholera, "first aid" stations have been opened in 17 different parts of the city; 42 disinfecting stations have also been established, of which 30 are situated in the central part of the town and 12 on the river. At each of these stations there is a medical officer, a disinfector, and a number of subordinate employés. In order to ensure an effective result not more than six separate operations of disinfection are permitted at each station in the course of 12 hours.

Cholera Cases in Germany and Austria-Hungary.

A single case of cholera occurred in Konigsberg on July 20th. The patient had arrived from Russia. Death occurred on the following day. The diagnosis of cholera was confirmed by bacteriological examination. News has also been received of a suspicious case of the disease at Lemberg, in Galicia, but details are wanting.

Plague in Adalia.

The first case here occurred (as stated in my last letter) on July 2nd. On the 12th another case was reported; the patient was a little girl, aged eight years, living in the Djami Atik quarter of the town; she apparently recovered. On July 19th, in the Yaniklik quarter, a third case was seen; the patient was a shoemaker, aged 16 years; he had been ill for four days; he died on the 23rd. Then on the 29th news was received of the following incident. An inhabitant of Adalia, a man, aged 35 years, left the town on the 27th, intending to drive to a place called Stanos, 60 kilometres from Adalia. He had been ill for some days before he started. After driving some 50 kilometres he died on the road. The municipal doctor, who happened to be in the neighbourhood, examined the body and pronounced that death was due to bubonic plague. On July 28th yet another case had been seen in Adalia itself; the patient was a boy, aged 14 years; he died on the 30th. There have thus been up to the present five cases of plague, with three deaths, in or near Adalia.

Cerebro spinal Meningitis in Arabia.

Within the last year or two epidemic cerebro-spinal meningitis has been showing unusual activity in many parts of the world. News has recently been received here of its appearance, in apparently a very fatal form, in a quite unexpected and little known country. Owing to the presence of plague in endemic form in the Assyr province of Arabia (situated between the Hedjaz on the north and the Yemen on the south) a sanitary officer in the service of the Constaninople Board of Health is permanently stationed at Ep-ha in that provincs. In June this official was requested by the Vali of Assyr to visit certain villages in the neighbourhood of Mihail, in the interior of the province, and report upon a very fatal outbreak of disease which had appeared there. In the first villages visited (those of Ma'ash, El-Daris, Mansab, Al-Fahma, and Ennus'b) no cases were seen, but in each there had been a heavy mortality from a disease which had in most instances caused death in 24 hours, or at most in a few days. The cemeteries showed, by the number of new graves, how high the mortality had been. In the next district visited, that of Al-Mohsin, nothing was seen but two cases of typhoid fever. Further travel in these regions was not without danger, but with the aid of Sheikh Faiz-bin-Nouh, a sheikh much venerated in those regions, it became possible to visit several villages in the districts of El-Hadjif and Tayal-Marwa. Here, in each village "and almost in every hut," patients were found, suffering from an acute disease which is said to have resembled in every way the epidemic form of cerebro-spinal meningitis. There were in each case high fever, accompanied with vomiting, excruciating headache and backache, contracture of the limbs, delirium, torpor, coma, and then death after a day's illness. The strongest and healthiest individuals did not escape; they were suddenly struck down (writes the author of this excellent report), crying, "Oh! my head!" or "Oh! my back! I have been shot in the back." The disease had apparently spread slowly in each village, and from one village to another. The district first affected had been that of Al-Fahma, then that of Al-Mohsin, and then that of Al-Hadjif. Although the population is extremely sparse—less than one person per square kilometre—the epidemic is said to have been "*une des plus terribles et ravageantes,*" as shown by the new graves in all the cemeteries. While still in these regions news was received of the appearance of the disease in the Al-Machwal district, and on visiting the villages in this district several of the first cases were seen; the symptoms were identical with those already described. It is noteworthy that both here and in the earlier villages visited an epidemic of enteric fever was prevalent at the same time as that of cerebro-spinal meningitis. Nothing was seen or heard of the prevalence of plague in any of the villages visited; but the tour did not extend to the country of the Beni Sheir, where the centres of endemic plague exist (or used to exist). That tribe or group of tribes was in active rebellion against the governing authorities, and it was impossible, without great risk, to penetrate to their settlements.

Constantinople, August 6th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

THE appointment of Dr. J. Michell Clarke to be the first Pro-Vice-Chancellor of the University of Bristol, which was briefly announced in my last letter, [illegible] than was possible at that time. The [illegible] proud of the honour done to on[illegible] generally agreed that the office could not be better filled. Dr. Michell Clarke has given an immense amount of time and pains during the past 25 years to the establishment and expansion of medical teaching in Bristol. He has taught medicine in the wards of the General Hospital for many years, and lately as professor of medicine at University College; and until it was found possible to appoint a whole-time professor of pathology, he held this office and taught pathology with conspicuous success. Prior to this he was lecturer on practical physiology, so that he has a very complete personal experience of the medical curriculum. Beyond this, he has taken a leading part in the heavy work of administration which has been necessary during the evolution of the University.—Lord Rosebery, as Chancellor of the University of London, has appointed Sir Arthur W. Rucker, M.A., D.Sc., LL.D., F.R S., to be his representative on the Court of the University of Bristol for a period of seven years.—The education committee of the Bristol city council has had a surprise in the shape of an application from the authorities of the University for the payment of the sum voted by the council several months ago This sum is about £7000, the proceeds of a penny rate, £3000 of which are earmarked for a scheme of scholarships, £4000 remaining for the general mainten[illegible] application was not expected yet, but the [illegible] rapid in its final stages, and the [illegible] Oct 1st. It is not likely that all [illegible] en shape sufficiently for use by [illegible] complete will presumably come [illegible] circumstances the education committee agrees to provide £2000 (half the general fund) in December, the special £3000 [illegible] waiting till the scholarship scheme is ready.

Bristol Royal Infirmary.

At the half-yearly meeting of the governors of the infirmary held on July 27th, Sir George White, the President, gave a brief account of the financial position during the first half of 1909. Comparing the figures with the same half of 1908, the total receipts were £8142, as against £8420 the preceding year; the ordinary expenditure was £8578, compared with £8457. Extraordinary expenditure to the extent of £948 was incurred in the starting of the nurses' training school and other items, leaving a balance due to treasurer of £1384. This makes an adverse balance of nearly £5000 accumulated during the last three years. Mr. Francis Tagart and Mr. Samuel White have each promised £1000 towards the extinction of this debt, and other promises amounting to £457 have also been received. The most hopeful feature of the financial outlook is the increase by £217 of the st [illegible] egacies were productive [illegible] White concluded with a [illegible] equate support, a statement of the work of the institution during the past half-year (1781 in-patients and 20,587 out-patients, as compared with 1747 and 20,227 in the corresponding half of 1908), and a brief reference to the building scheme. This has progressed as far as the demolition of the houses which occupied the *site to be devoted to the projected new* premises, the detailed specifications for which are being prepared. Building tenders will be asked for in a few months. After the general meeting a special meeting was held to elect Mr. G. Munro Smith consulting surgeon on [illegible] replied. Mr. H. F. Mole, who has for some years been assistant surgeon, was elected to the full staff, and Mr. C. F. Walters, surgical registrar to the infirmary, was elected assistant surgeon.

Death of Mr. Edward Benjamin Steele-Perkins, L.S.A. Lond.

Mr. E. B. Steele-Perkins, who died at his residence, Wilton-place, Exeter, on July 30th, in his sixty-eighth year, was a member of an old Exeter family. He received his medical education at Charing Cross Hospital, and after qualifying in 1876 joined his father in practice at Exeter. For nearly 40 years he was a familiar figure in that city, and his geniality won him many friends. He was keenly interested in the Volunteer movement and for many years held a captaincy in the 1st Devon Artillery Volunteers, retiring about ten years ago with the honorary rank of major. His father, the late Dr. John Steele-Perkins, was one of the earlies [illegible] Mr. Steele-Perkins had a large [illegible] s honorary surgeon to the Devon [illegible] Refuge, and also medical examiner for the Royal Navy and Royal Marines. He was a "freeman" of the city of Exeter, for many years represented St. Sidwell's ward in the city council, and was held in high respect. He leaves a widow and two daughters.

Public Health in Honiton District.

At a recent meeting of the Honiton (Devon) rural district council a letter was read from Mr. F. R. S. Cosens, the secretary of the Honiton and Axminster Unions Medical Association, stating that at a meeting of the medical men of the Honiton and Axminster unions a resolution was passed urging the provision of an isolation hospital for the Honiton [illegible] urban, Ottery St. Mary urban, and [illegible] the appoint[illegible] who should [illegible] vote all his time to public health work.

The Pearn Convalescent Home, near Plymouth.

The annual meeting of the subscribers of this institution was held recently under the Presidency of Vice-Admiral J. E. Maitland Wilson. The medical report stated that during 1908 the patients admitted numbered 496, compared with 491 in 1907. 307 patients were admitted from the South Devon and East Cornwall Hospital, 172 from the Royal Albert Hospital, Devonport, and 17 from the Plymouth Eye Infirmary. 61 nurses from these hospitals were also received during the year. The expenditure for the year was £1123, the average cost of each patient being *2s. 6d.* per day.

The Totnes Cottage Hospital.

At the annual meeting of the subscribers of the Totnes (Devon) Cottage Hospital the following members of the honorary medical staff, whose term of office had expired, were re-elected: Dr. K. R. Smith, Dr. G. J. Gibson, Dr. W. R. Edmond, Dr. W. Chapman, and Mr. H. S. Johnson.

The Tour of the "E. M. I."

The party of foreign medical men who have been touring England under the auspices of the "Enseignement Médico-Mutuel Internationale" arrived at Bristol on August 15th under the guidance of Dr. Etienne Bazot of Paris. They visited the Royal Infirmary and were conducted through that institution by members of the honorary staff. They then drove on to the General Hospital where they were received by the president, Mr. J. Storrs [illegible] members of the visiting staff. [illegible] institution and expressed their [illegible] operating theatres, and the nurs [illegible] Royal Hotel, to which represen [illegible] invited, they made a tour of Clifton which included the Zoological Gardens, and were finally entertained at the houses of several medical men who had conducted them over the institutions in the morning.

August 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Infant Visitation in Glasgow.

UNDER the scheme of visitation of the Public Health [illegible] ector calls at every house [illegible] er this arrangement 12,954 [illegible] male inspectors during the [illegible] proved to be duplicates of [illegible] ere not visited for various [illegible] given, while 737 more [illegible] no less than 96 per cent had [illegible] in the early weeks of life. [illegible] been given by the Glasgow Infant Health Visitors' Association. Of this association there are now 15 different branches supplying voluntary visitors to the number of 300, who undertake visitation in 19 wards or districts of wards. While the visitors are untrained in public health work, and no standard of training can be insisted on beyond a familiarity with the requirements of district visitation, there is every reason to believe that the influence of an educated and sympathetic visitor cannot fail to operate for good in the homes of the poor. Information regarding the cases to be visited is sent by the health office to the secretaries of the various branches of the association, [illegible] turning reports to the [illegible] The cards forwarded [illegible] nsist of a yellow card which is [illegible] card which is f [illegible] cards may be ret [illegible] st the visitors as [illegible] y are only for [illegible] health office wher [illegible] The complete r [illegible] yellow card and [illegible] to the health office immediately the baby has completed his twelfth month.

Greenock and Phthisis Cases.

In a report to the Greenock corporation the medical officer of health for the burgh states that even 12 beds in the Combination Hospital would enable the health authorities to institute *a definite campaign against phthisis*. The cost is estimated at £620. It is proposed to establish a dispensary, the upkeep of which would probably not exceed £100 per annum.

Large Donation to Dundee Royal Infirmary.

At a meeting of the directors of the Dundee Royal Infirmary held on August 12th Mr. George Duncan, one of the directors, read a letter from Miss Duncan of Drumforte, intimating a donation of £4200 to the funds of the infirmary for the purpose of endowing two beds in memory of, and to be named after, Miss Duncan's late brothers, Mr. James Duncan of Drumforte and Indanstone, and Mr. George Duncan, banker, Alyth; and two cots in the children's ward, one to be named after her late sister, Miss Marjory Duncan, and the other to be named after herself, preference to be given to patients from Alyth and Blackwater districts. On the m [illegible] chairman, the directors resolved to record their [illegible] a time [illegible] since its inception not a single case it has undertaken to defend has been lost, and the finances have been administered so faithfully that to-day there are several thousand dollars to the good of the society.—Another important meeting also will be the meeting of the Milk Commission of the Canadian Medical Association. During the past year this Commission has done a great deal of work, not all of an educative character. It is now proposed to form subcommittees in all the places of importance in Canada and to push along the campaign for clean milk. The Commission also advocates the pasteurisation of clean milk, and the success it is attaining is seen in the fact that the Hospital for Sick Children, Toronto, is establishing a pasteurisation plant, and two large dairies are adopting a similar course.

A French Decoration for a Surgeon of Montreal.

Dr. J. N. Roy, Montreal, has recently received from the French Government the Order of the Dragon de l'Annam. This decoration, which has not been previously conferred on any Canadian, is largely bestowed for military service. Some four years ago Dr. Roy, while making a trip round the world and being in Chinese waters, acted as emergency surgeon to a French warship which had been wrecked through an explosion. He attended for some days to about 20 injured sailors and accompanied them to Tonking where they were placed in the military hospital.

New Brunswick Medical Association.

The annual meeting of the New Brunswick Medical Association was held in St. John, N.B., on July 20th and 21st, under the presidency of Dr. J. R. McIntosh. Dr. S. Skinner, of St. John, in presenting a paper on Public Health, regretted that St. John had no medical inspection of schools. He also spoke of the dust in the streets and street noises, which he claimed were a menace to the health of the people. The report of the registrar of the society referred to the recent attempt to have the medical law of the province amended, but owing to strong opposition this had to be abandoned. Steps had been taken recently to establish the five-year curriculum in New Brunswick and so bring that province into line with the other provinces of the Dominion in this respect. It was decided to meet in St. John again next year as the Maritime Medical Association will meet there then; and the Canadian Medical Association will also be invited to meet in 1910 there, as the national medical body has not met in St. John since 1894. The following officers were elected: President, Dr. H. A. Murray, Fredericton Junction; first vice-president, Dr. O. T. Purdy, Moncton; second vice-president, Dr. G. G. Melvin, St. John; treasurer, Dr. D. E. Berryman, St. John; corresponding secretary, Dr. J. S. Bentley, St. John; and recording secretary, Dr. G. G. Corbet, St. John.

Maritime Medical Association.

The annual meeting of the Maritime Medical Association met in Charlottetown, P.E.I., on July 15th and 16th. A communication was read from the general secretary of the Canadian Medical Association concerning the affiliation of the maritime medical societies with the national medical body. No action was taken in the matter at that meeting. Another matter of interest brought up was the subject of reciprocal registration with Great Britain. This was introduced by a communication from the British Medical Association, which called attention to the fact that the five-year [illegible]e adopted to secure reciprocal [illegible]ral Medical Council of Great [illegible] was also submitted advocating [illegible] amongst the provinces of the [illegible] was referred to a committee of three. Dr. F. Montizambert, the Director-General of Public Health in Canada, was present and delivered an address on tuberculosis He believed that greater good could be accomplished by house visitation by nurses than by sanatoriums. Dr. Black, M.P., Windsor, N.S., advocated a bureau of health for Canada. An address was also delivered by Lieutenant-Colonel Carleton Jones, M.D., Director-General of the Canadian Army Medical Services, who referred to the laboratory being established by the Canadian Department of Militia in connexion with the Army Medical Corps. The following officers were elected for next year:—President: Dr. W. A. Ferguson, Moncton, N.B. Vice-Presidents: Dr. J. G. Macdonald, Amherst, N.S.; Dr. A. G. Ferguson, Dalhousie; and Dr. A. A. MacLellan, Summerside, P.E.I. Treasurer: Dr. D. D. Corbet, St. John, N.B. Secretary: Dr. G. G. Melvin, St. John.

Ontario Medical Council.

One of the most important subjects discussed at the annual meeting of the Ontario Medical Council in Toronto in July was that of restricting the practice of the osteopaths. In British Columbia, a campaign is being waged against the osteopaths and they have been given until September to go out of business. As a consequence, several have already left Vancouver and Victoria for American cities. One of the clauses in the report of the [illegible] Ontario Medical Council advised [illegible] be taken against these self-same [illegible] have been thriving all too plentifully in Toronto and other Ontario cities. The solicitor to the Medical Council has given his opinion that the osteopaths are carrying on business in contravention of the Ontario Medical Act. The matter was placed in the hands of the executive and action may be expected at any time. The Council also took up the question of reciprocity with the province of Manitoba and other Western Provinces. As a result, two special delegates were appointed by the Council from amongst its members to proceed to the annual meeting of the Canadian Medical Association at Winnipeg on August 23rd, 24th, and 25th, to confer with representatives from the Western Provinces. The question of reciprocity with Great Britain was mentioned, but the committee in charge asked that further time be given them to prepare a report. Reciprocity was also discussed with the State of Michigan, U.S.A., but the Council was of the opinion that the time was not opportune for any such measure. A long and at times animated discussion took place on what action the Council should take on criminal cases, several medical men having been before the law courts recently in connexion with abortion cases. Whilst the feeling ran strongly to prompt action in the way of removal from the Register, it was thought best to proceed with all due caution until the courts had established the guilt of such parties. Dr. E. P. Hardy (Toronto) was elected President and Dr. John L. Bray (Toronto) was re-elected registrar.

The Toronto General Hospital and the University of Toronto.

The *Canadian Practitioner and Review* for August, in an editorial article on this subject, says that by a recent agreement arrived at by the governors of the University and the board of trustees of the hospital the University will secure the south-west portion of the new hospital site for medical buildings, and for this privilege will make an annual grant of about $15,000 to the hospital for 40 years. By this arrangement the chief professors of medicine and surgery will be heads of services in the hospital and also heads of its special departments. Four members of the board of governors and four members of the board of trustees of the hospital will act as a joint committee to make recommendations for other appointments. Ground is now being prepared for the erection of the new Toronto General Hospital which is to cost about $2,200,000. The amount of subscriptions received at present is $1,200,000. The old hospital property will produce $300,000, and the recent agreement between the two institutions will be security for at least another $300,000. The new hospital will probably accommodate 500 patients—about 50 more than the present institution; and there is a feeling amongst some medical men that the old building should be still used for hospital purposes to accommodate the growing needs of the eastern portion of the city.

Toronto, August 3rd.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Lymphangioplasty for Elephantiasis.

AT a recent meeting of the Burma branch of the British Medical Association an interesting case was shown, the patient being an Indian, aged 35 years, belonging to the military lines, who was recently operated on for elephantiasis of the right leg, from which he had been suffering for the past few years, the operator being Major E. R. Rost, I.M.S., civil surgeon, Civil General Hospital, Rangoon. So far the results of the operation seem very satisfactory. The whole operation did not take over 20 minutes and the patient experienced no distressing symptoms. The operation consisted of the introduction of several silk ligatures into the subcutaneous tissue of the diseased foot, which ligatures were carried up the leg and inserted into the muscles higher up. They [illegible] pass owing to the block [illegible] ligatures by capillary a[illegible] n days after the operati[illegible] ie leg, which previously [illegible] thickness of the left leg, has been almost reduced to its normal state. [illegible] is due to Mr. Sampson [illegible] or the relief of "brawny [illegible] g in the Cancer Research [illegible] al, as he recorded in THE LANCET, Vol. I., 1908, p. 784. He subsequently [illegible] encouraging to report a confi[illegible] from a country in which elephantiasis is so rife as in India.

Plague.

[illegible] week ending July 3rd show 478 [illegible] the week preceding. Bombay [illegible] lras 41, Bengal 60, the United Provinces 80, the Punjab 71, Burma 86, and Mysore State 60.

The Health of the Jails.

[illegible] y apparent in this [illegible] ement of jails in [illegible] sions to the jails [illegible] per cent. higher [illegible] verage number of [illegible] er. The increase in admissions was particularly marked in certain of the districts that suffered severely from famine—Bahraich, Sitapur, and Gonda, and also in Hardoi. These districts also sustained the depredations of gangs of dacoits who were driven to crime by the famine. The death-rate of the jails was 60 [illegible] result direc[illegible] prisoners. [illegible] to jail has [illegible] being shown for this fact.

A Vaccine for Dysentery.

In the [illegible] Association it is mentioned [illegible] the Indian Medical Service h[illegible] with regard to a vaccine w[illegible] nsiderable value in the treatment of dysentery. The vaccine is the preparation of an officer of the Indian Medical Service, but is not availabl[illegible] districts. In a letter of June [illegible] with the Government o[illegible] has been referred, stated that pending the completion of a special inquiry into the etiology of dysentery in India now in progress at the Central Research Institute it was not considered advisable to issue dysentery vaccine.

Infant Mortality in Burma.

Are a hot, dry climate and low rainfall the natural conditions most prejudicial to infant life? This is a problem propounded by Major Williams, I.M.S., the Sanitary Commissioner of Burma, in his annual report. The death-rate of infants under 12 months for Burma in 1908 was 208·96 per 1000, and it appears that the more northerly the situation of the town, and consequently the drier and hotter the climate, the higher the death-rate. Another instance which Major Williams observes as producing an obviously deleterious result on infant life is the congestion of population and buildings in confined quarters in towns. The Lieutenant-Governor of Burma is, however, sceptical of the Sanitary Commissioner's conclusions. It is notorious that there are probably no people which exhibit greater fondness for children than the Burmans, a[illegible] believes that a great deal of t[illegible] proper feeding through ignoranc[illegible] are at present in a shockingly [illegible] their notions of hygiene, and it is [illegible] they cannot look after their you[illegible] their very insanitary customs. Meanwhile, every effort is being made to cultivate in the Burmans some of the fundamentals of sanitary knowledge, and it seems to be a good sign that measures which have been taken on these lines for the benefit of the rising generation in the Burmese schools have been successful.

The Accommodation for Soldiers' Families in the Hills.

The severe sickness that followed last year's rains through the length and breadth of Upper India has made the demand for hill accommodation for soldiers' families this year very considerable. There are always a large number of soldiers' wives who prefer the heat in the company of their husbands to the long and often dreary separation of a move to the hills. Soldiers and non-commissioned officers, too, often find that the cost of a home in the hills as well as in the plains is a very severe strain on their resources. This year, however, so great has been the demand for hill accommodation that there has been much difficulty in meeting it. The accommodation provided, considerable though it is, has never been adequate, and it has to be supplemented with tents. Not unnaturally soldiers' wives have a great antipathy to tents in the hills. They do not like the cold of the first weeks, when their blanket equipment is often inadequate, and they find the rains very wretched. The class of servants and odd natives that frequent such camps are notoriously bad, and thefts in tents are a constant source of complaint. It would seem to be very desirable that the amount of hut accommodation for families in the hills should be augmented, so that the major portion of the families might be saved from the dreary heat of the plains. The families of the rank and file are of a far superior class than in years gone by, and it is to the advantage of the army that they should be well accommodated, while it is distinctly to the advantage of India that the children should be reared in health-giving surroundings and given a fair chance to grow up as useful members of the community.

August 13th.

Obituary.

THEODORE DAVIS, M.D. LOND., F.R.C.S. ENG.,

CONSULTING SURGEON, CLEVEDON (SOMERSET) DISPENSARY AND CLEVEDON COTTAGE HOSPITAL.

Dr. Theodore Davis, one of the best-known and highly respected medical practitioners of Clevedon and the neighbourhood, died at his residence, Walton-in-Gordano, Clevedon, on August 11th, in his seventy-sixth year. He was the son of the late Dr. J. Davis of Clevedon, and received his medical education at Queen's College, Birmingham, and St. Bartholomew's Hospital, London. He obtained the F.R.C.S. Eng. in 1859, and two years later took his London doctorate. Dr. Davis shortly afterwards commenced practice at Clevedon, where he soon obtained an honourable reputation and a leading position in the district, and was often sought in consultation by his professional brethren. Dr. Davis was on the honorary staff of the local hospital and also of the dispensary. He had retired from active work for some years owing to failing health. Dr. Davis will be [illegible] is felt there fo[illegible] took place at [illegible] largely attended.

EDWARD MORRIS, M.R.C.S. ENG., L.S.A.

Mr. E. Morris, who died at his residence, 5, Caprera-terrace, North-road, Plymouth, on August 10th, from heart failure, was a veteran of the medical profession, for he was born on March 15th, 1827, at Devonport. He was educated at the Plymouth Grammar [illegible] to Mr. J. Whipple, surgeo[illegible] mew's Hospital, taking th[illegible] tion in 1854 and 1856 respectively. Shortly after qualifying [illegible] Mr. Morris was for many years medical emigration officer under the Board of Trade. He occupied a prominent position in the "Three Towns," where he had an extensive practice and a considerable reputation. Mr. Morris never married.

For, some years he had retired from all active work, and for the past three years had suffered from cardiac disease. The funeral took place on August 13th and was very largely attended by many anxious to show respect for an old friend who had died full of years and honour.

Medical News.

UNIVERSITY OF LONDON.—At examinations for internal and external students held in July the following candidates were successful:—

FIRST EXAMINATION FOR MEDICAL DEGREES.

Douglas Reid Alexander, Epsom College; ‡Elizabeth Labrey Ashby, University of Birmingham; Frank Montague Barnes, St. Thomas's Hospital; Irene Bastow, London (Royal Free Hospital) School of Medicine for Women; William Roy Blore, The Leys, Cambridge; ‡John Bostock, London Hospital; †Gerald Kessick Bowes, Epsom College; Alice Dorothea Brooks, London (Royal Free Hospital) School of Medicine for Women; Frederick Charles Sedgwick Broome, Guy's Hospital; Owen Deane Brownfield, Epsom College; Isabel Florence Buckle, London (Royal Free Hospital) School of Medicine for Women; William Burt, St. Thomas's Hospital; Frederick Wyndham Chamberlain, Middlesex Hospital; Harold Garrett Chaplin, St. Thomas's Hospital; John Eric Cheesman, [illegible] Harold Aylmer De Morgan, [illegible] O. Doorly, St. Thomas's [illegible] 's School; Ahmed Fahmi [illegible] University of Birmingham; [illegible] Hospital; Hugh James Orr, [illegible] rles Hamilton Gould, Guy's [illegible] sity College, Cardiff; *Mary Esther Harding, London (Royal Free Hospital) School of Medicine for Women; John Richard Harris and †Claude Charles Harrison, [illegible] Horace William Hay, University [illegible] tchings, Guy's Hospital; Alec George [illegible] †Henry Julyan Hoyte, University [illegible] Hospital; Iorwerth Hubert [illegible] College and private study; [illegible] Technical Schools; *Norman [illegible] St. Thomas's Hospital; William Francis MacAlevey, University of Birmingham; Jivraj Narayan Mehta, Grant Medical College, Bombay, and University Tutorial College; James York Moore, Guy's Hospital; Arthur Daniel Morris, University College, Cardiff; Purushottam Tulsibhai Patel, Grant Medical College, Bombay, and University Tutorial College; Thomas Bond Paul, Middlesex Hospital; Innes Hope Pearse, London (Royal Free Hospital) School of Medicine for Women; Julian Lionel Priston, London Hospital; Charles Edgecumbe Procter, Epsom College; Frederick Tavinor Rees, University College, Cardiff; †Robert Edward Roberts, University of Liverpool; James Albert Robinson and William Eric Roper Saunders, St. Bartholomew's Hospital; Henry Richard Sheppard, Brighton Municipal Technical College; Reginald Hugh Simpson, Epsom College, John Smith Sloper, St. Thomas's Hospital; †Edward Seguier Sowerby, University College, Bristol; Clifford William Sparks, St. Thomas's Hospital; John Eric Stacey, University of Sheffield; Grace Stapleton, London (Royal Free Hospital) School of Medicine for Women; John Stephenson, Alleyn's School, Dulwich; William Edmund Taylor, University College, Bristol; Naomi Tribe, London (Royal Free Hospital) School of Medicine for Women; Henry Parks Whitworth, Guy's Hospital; Gerald Richard Courtenay Wilson, St. Thomas's Hospital; Arthur Graham Winter, London Hospital; and Herbert Gregory Winter, Epsom College.

* Awarded a mark of distinction in organic chemistry.
† Awarded a mark of distinction in physics.
‡ Awarded a mark of distinction in general biology.

The following students who took a portion of the examination under Old Regulations have now completed it:—

William Claude Percy [illegible] ge; Thomas David Collis Barry, private [illegible] Bevan-Brown, Guy's Hospital; Ursula Po [illegible] Royal Free Hospital) School of Medicine f [illegible] Ying-Jue Oieh, King [illegible] College, Cardiff; Dora Challis Colebrook, Lo [illegible] pital) School of Medicine for Women; [illegible] Cooper and Stephen Andrew Cornelius, University College; John Kenyon Davies, University College, Cardiff; Charles Frederick Hacker, University College and Nort [illegible] tute; Stanley Sextus B. Harrison, Guy's [illegible] gdon, King's College; Reginald Walter [illegible] llege, Cardiff; Desmond Manus MacMan [illegible] ladys Matthews, Ladies' College, Cheltenha [illegible] rivate study; John Ernest Pearce, Brigh [illegible] and private study; Stanley Hugh Robinson, Guy's Hospital; Gordon Wilfrid R. Rudkin and Eric Arnold Scott, University College; Gerald Davenant Shann and Maurice Ulick Wilson, King's College; and Siong Yew Wong, St. Thomas's Hospital.

The following students who took a portion of the examination under Old Regulations have now qualified as follows:—

Inorganic Chemistry.—John Prichard Bracken (*p*), University College; and John Alexander Pridham (*p*), Weymouth College.
Physics.—Ernest James Coombe (*c*), King's College; and Frank Bramshaw Gilhespy (*b*), University College.
Gen [illegible] Margaret Burns (*c*), London (Royal Fr [illegible] icine for Women.

p. This candidate had already passed in experimental physics.
c. This candidate had already passed in inorganic chemistry.
b. This candidate had already passed in biology.

SECOND EXAMINATION FOR MEDICAL DEGREES.

Part I.—Basil William Armstrong, St. Mary's Hospital; John Rawlings Barrow-Clough, Guy's Hospital; Robert Maitland Beath, Queen's College, Belfast; Kenneth Biggs, London Hospital; Percy Butler, University College; George Maclean Campbell and Alice [illegible] llege, Bristol; John Archer Cowan, [illegible] Joseph Cronin, London Hospital; [illegible] Thomas's Hospital; Hector Wynne Davies, University College; Henrietta Frances Davies, London (Royal Free Hospital) School of Medicine for Women; John Yerbury Dent, King's College; George Dunluce Eccles, Guy's Hospital; Herbert Thomas F [illegible] Walter Stuart I [illegible] London Hospital; [illegible] Foley, St. Thomas's Hospital; Katherine Mary Lovell Gamgee, University College; Georg Arnold Gassmann, London Hospital; Edward Alexander Marie J. Goldie, University College; Una Griffin, London (Royal Free Hospital) School of Medicine for Women; Robert Lister Horton, University College; Richard Orthin Hilton Jones, University of Liverpool and private study; Mildred Archer Jukes, London (Royal Free Hospital) School of Medicine for Women; Rustam Merwan Kharegat, University College; William Joseph Teil Kimber, St. Thomas's Hospital; Eric Pierpoint Langley, St. Mary's Hospital; Edward Athol C. Langton, St. Bartholomew's Hospital; Constance Leetham, London (Royal Free Hospital) School of Medicine for Women; William Leslie, Charing Cross Hospital; Eric Delafield Lindow, King's College; Muriel Annie Lloyd and Helena Rosa Lowenfold, London (Royal Free Hospital) School of Medicine for Women; Arthur G. Maitland-Jones, London Hospital; Refna Mallet, London (Royal Free Hospital) School of Medicine for Women; Lionel Arthur Martin, University College; George Sefton Miller, Guy's Hospital; Wilfrid Egerton Milligan, St. Thomas's Hospital; Donald Ewart Morley, London Hospital; Edith Mary Nesbitt Moss, University College, Nottingham; Cyril Eaton Petley, Guy's Hospital; John Alexander Poole, St. Bartholomew's Hospital; Edna Mary Powell, London (Royal Free Hospital) School of Medicine for Women; Richard Amyas Preston, University of Leeds and private study; John Beaufoy Randall, St. Bartholomew's Hospital; Winifred Mary Ray, London (Royal Free Hospital) School of Medicine for Women; Leslie Norman Reece, St. Thomas's Hospital; Francis Charles Robbs, St. Mary's Hospital; Cedric Sydney Lane Roberts, Guy's Hospital; George Henry Roberts, St. Thomas's Hospital; Henry Colwell Rook, John Alfred Ryle, Evelyn Dennis Scott, Cyril Sherris, and *Arthur Joseph E. Smith, Guy's Hospital; Harold Edward Smith, University of Sheffield; Margaret Edith Elliott Smith, [illegible] of Medicine for Women; Sidn [illegible] Henry Dakin Smith, Universit [illegible] University of Birmingham [illegible] St. Bartholomew's Hospital; [illegible] of Manchester, Manchester Municipal Technical School and Private Study; James Robert Karran Thomson, London Hospital; Thomas Burdock Vaile, St. Bartholomew's Hospital; Mary Alice Van Ingen, London (Royal Free Hospital) School of Medicine for Women; Herman Crowther [illegible] Liverpool; Ernest Wentworth Wade, [illegible] and Private Study; Alfred Stewart W [illegible] n Richard Menzies Whigham, St. Mary [illegible] Wilkinson and John Douglas Wilkinson, St. Thomas's Hospital; Alfred Wills, Guy's Hospital; Alan Wilson, University College; Oscar Reginald Lewis Wilson, Guy's Hospital; and Arthur Wai-tak Woo, London Hospital.

* Awarded a mark of distinction.

Among the successful candidates in the scholarships examination were the following:—

Physics.—Lewis Simons (Neil [illegible] g's College.
Chemistry.—John Edmund I [illegible] holarship) and Hubert Arthur Harry Howa [illegible]
Botany.—*Gertrude Maria Talbot, University College; and *Elizabeth Mary Thomas, Birkbeck College and South-Western Polytechnic Institute.

* A Gilchrist Scholarship is divided between these two candidates

THE death of another centenarian is reported, Mrs. Jane Allen having died at Scarborough on August 13th in her 101st year.

NORFOLK AND NORWICH HOSPITAL.—On August 14th the Charity Football Cup Competition Committee existing in connexion with this hospital presented the institution with a cheque for £130, making a total of £730 which has been collected through this channel during six years. This amount is contributed chiefly by the working classes and represents the proceeds of the "gate" on the day of the competition for the Charity Cup. Mr. Leathes Prior presented the cheque on behalf of the working men of Norwich.

KENT COUNTY COUNCIL.—A committee of the Kent County Council has recommended the council to pass a resolution to group Queenborough, Sittingbourne, Milton Regis, and Milton Rural under one whole-time medical officer. It has also directed that a letter should be sent to the boards of guardians in the county of Kent on the subject of the payment of fees to medical men summoned by midwives to assist them in difficult cases under the provisions of the Midwives Act, stating that it was desirable for medical men to be paid for such services, as it did not appear that guardians exercised their powers to make these payments (subject to recovery of fees, where possible, from the patient), as frequently as was desirable.

THE BURTON-ON-TRENT INFIRMARY.—The committee of this institution has decided to make some necessary enlargements in the out-patient department for provision of better accommodation for X ray and other work. Plans have been prepared by Mr. H. Beck, the hospital's architect, and a tender of £700 for the improvements has been accepted.

PTOMAINE POISONING AT COLCHESTER.—A disturbing incident occurred at Colchester on August 15th, nearly 70 men in the barracks having been seized with symptoms suggesting ptomaine poisoning after eating a kedgeree of fish and rice. They were admitted to the Garrison Hospital, but they recovered sufficiently to be discharged shortly afterwards.

FATAL PANIC AT A KINEMATOGRAPH EXHIBITION.—On August 14th an unfortunate panic occurred at the Victoria Hall, Southsea, during the progress of a kinematograph performance. The accidental ignition of the film excited sudden alarm, although the fire was extinguished by means immediately available. A woman, however, shouted "Fire," which caused a stampede amongst a number of children in the gallery, and rushing downstairs many of them became jammed in the entrance to the street door, with the result that the 11-year-old son of a workman was killed, and eight others were injured more or less severely. No blame appears to have attached to the management of the exhibition in the precautions taken to prevent the disaster.

PLUMBING CLASSES IN LANCASHIRE.—Sir Henry Hibbert, chairman of the Lancashire education committee, distributed at Preston last week the prizes won by students at the plumbing classes in a special series of examinations in practical work, conducted at the chief educational centres in Lancashire. Sir Henry Hibbert said that, so far as he could gather, Lancashire stood alone at present in regard to these practical tests of workmanship. The reason was that the county education committee attached a high degree of importance to successful craftsmanship in plumbing both from the hygienic and commercial points of view. They had to a very large extent been helped by the Worshipful Company of Plumbers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Lunacy Returns.

THE annual report of the Commissioners in Lunacy has just been issued as a Parliamentary Blue book. It is stated therein that there were known to be under care on Jan 1st, 1909, in England and Wales 128,787 persons certified as insane The number exceeds by 2703 the number of insane recorded on Jan. 1st, 1908—namely, 126,084. The pauper patients on Jan. 1st, 1909, were 117,377, or 91·1 per cent. of all certified insane. The Commissioners make allusion to the report of the Royal Commission on the Care and Control of the Feeble-minded and express agreement with the suggestion to permit the courts to have the condition of mental defectives inquired into at an earlier stage than is now done.

Metropolitan Ambulances Bill.

The Metropolitan Ambulances Bill has passed through one of the Standing Committees of the House of Commons. This is the measure which Sir WILLIAM COLLINS introduced some time ago to enable the *London County Council* to establish and maintain an ambulance service in London. There has been a difference of opinion as to what authority should undertake this work and this was reflected in the discussion on the Bill Mr. PEEL, who has introduced a Bill to entrust the Metropolitan Asylums Board with the duty, moved the rejection of the first clause which gives to the London County Council power to establish the ambulance service. He quoted the finding of the majority of the recent Departmental Committee in support of his argument that the work should be carried out by the Metropolitan Asylums Board. Sir WILLIAM COLLINS strongly opposed Mr. PEEL's views. He expressed the opinion that the London County Council could carry on the ambulance service much more economically than the Asylums Board In insisting on the need for legislation on the subject, he mentioned that the number of accidents on the *streets of London* was going up by leaps and bounds. Whereas in 1905 they amounted to 10,260, in 1906 they reached 12,237, and last year they totalled 14,323. Mr. GLADSTONE, the Home Secretary, gave his support to the proposals of the Bill of Sir WILLIAM COLLINS, but he emphasised the fact that he did not commit the Government to it. He stated that he had given the whole question careful consideration, and had come to the conclusion that the London County Council as a rating authority was the best body to which to entrust the administration of the ambulances. The right honourable gentleman asked the Committee not to delay the Bill as legislation was urgent. Before the division was taken Sir WILLIAM COLLINS stated that several well-known philanthropists had expressed the intention of offering electric motor ambulances for the service. Clause I. was ultimately carried by 28 votes to 1. On the motion of Mr. GLADSTONE, the following new clause was inserted in the Bill:—"The London County Council may allow the ambulance service established under this Act to be used, on such terms and conditions as may be agreed upon, by any local authority having powers under section fifty of the Public Health Acts Amendment Act, 1907." The Bill as amended was ordered to be reported to the House.

Glasgow Hospital for Skin Diseases.

The Glasgow Hospital for Skin Diseases Confirmation Order Bill has passed through all its stages in both Houses of Parliament and has received the Royal Assent.

The Midwives Act.

The report of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act, 1902, has been presented to Parliament.

Asylum Officers' Superannuation.

A special report has been brought forward by the Select Committee of the House of Commons on the Asylum Officers' Superannuation Bill. The Committee has found that even before it entered upon its inquiry there was a considerable accumulation both of precedent and authority in favour of the principle that a system of substantial superannuation allowances for meritorious service in public asylums, certain in its operation and contributory in its method, was desirable, just, and expedient. The Committee has come to a strong and unanimous opinion that legislative effect should forthwith be given to this principle. It has further endeavoured to amend the Bill introduced by Sir W. COLLINS to deal with the superannuation of asylum officers in such a way as to apply to the special exigencies and requirements of the asylum service, *mutatis mutandis*, the methods already approved in the case of the Poor-law and the police.

HOUSE OF COMMONS.

THURSDAY, AUGUST 12TH.

Housing and Town Planning Bill.

Answering Lord ROBERT CECIL, Mr. ASQUITH stated that he could not say when the committee stage of the Housing and Town Planning Bill would be taken.

Mr. WEDGWOOD: In view of the change which the proposals of the Government for a complete valuation will make will the right honourable gentleman postpone this Bill until next session in order to take advantage of that valuation?

Mr. ASQUITH: No, sir.

The Public Analyst for the Isle of Wight.

[illegible]

circumstances I do not feel able
objections are in no way affecte
Buchanan's report.

Tetra chloride of Carbon as a Hair-wash.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether he was aware of the extensive use of tetrachloride of carbon as a hair-wash, whether his attention had been called to a recent death of a young lady while her hair was being shampooed with this compound; whether his attention had been directed to the poisonous properties of carbon tetra-chloride; whether any restrictions upon the sale or use of this compound at present existed; and whether he proposed to take any steps in the matter.—Mr. GLADSTONE wrote in reply: My attention has been called to the use of tetra-chloride of carbon as a hair-wash, to the very great danger involved, and to the death referred to by my honourable friend. I am informed by the Privy Council that tetra chloride of carbon is not a poison within the meaning of the Pharmacy Acts, and there are, therefore, no restrictions as to its sale. As regards the steps to be taken in the matter, I can only say that the Director of Public Prosecutions has the question of a prosecution now under his consideration.

TUESDAY, AUGUST 17TH.

[illegible]

month.—Mr. [illegible] replied: Forty-eight
Of these six had
, and 21 had less
y recently joined

the corps, and some officers had returned during the year from stations abroad where they had already had the leave to which they were entitled.

The Tsetse Fly and Sleeping Sickness.

Mr. REES asked the Under Secretary of State for the Colonies whether the Government had yet acquired any reliable information regarding the relations between big game and tsetse fly in Central Africa; and if so what bearing such information had upon the policy of game preservation and of prevention of sleeping sickness.—Colonel SEELY replied: The relation between big game and the tsetse fly in Central Africa is a much-debated qu[illegible] [illegible] by the Secre[illegible] [illegible] research in [illegible] [illegible]on, amongst others, will receive their earnest consideration.

A Consignment of Frozen Meat.

Mr. STANIER asked the President of the Local Government Board whether he could publish the report of the medical officer of health on the consignment of frozen meat landed by the Peninsular and Oriental steamer *Palermo* at the Royal Albert Docks from China.—Mr. BURNS replied: I have no doubt that the medical officer of health of the City will ultimately deal with this matter in the report to the sanitary committee of the Corporation which will be printed and issued in the usual way. But no general report can be made for some time as the carcasses will not be thawed and examined all at once, but only as they are required for trade purposes. So far less than 5 per cent. of them have been thawed and examined.

WEDNESDAY, AUGUST 18TH.

[illegible] *Army.*

Sir WILLIAM [illegible] State for War whether he would state wh[illegible] [illegible]er treatment to which the soldiers treated at Millbank Hospital as typhoid carriers, on whom [illegible] with antityphoid injections were made, had [illegible] [illegible]ether he would lay upon the table papers showing [illegible] by the various methods employed in these cases in continuation of those already laid.—Mr. HALDANE wrote in reply: The later treatment alluded to consists in treating the urinary cases with sodium benzoate and acid sodium phosphate. X ray treatment is being tried in one of the intestinal cases with marked gall-bladder symptoms. It is yet too early to speak of results, but I shall be prepared to lay papers on the subject at a later period.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BARTLETT, CHARLES E., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Chepstow (Mon.) Board of Guardians.

BROWNE, FRANCIS JAMES, M.B., Ch.B. Aberd., has been appointed District Medical Officer by the Bedwellty (Mon.) Board of Guardians.

DAVSON, FREDERICK ADAMS, M.D., C.M. Aberd., M.R.C.S., has been [illegible] Medical Officer of Health for the Dartmouth [illegible] [illegible]rity.

[illegible] C.S. Eng., L.R.C.P. Lond., [illegible] Post Office at Tenby.

[illegible] [illegible]ppointed Junior Assistant Medical Officer at Sunnyside Asylum, Montrose.

GRAY, WALTER GORDON, L.R.C.P., L.M. Edin., M.R.C.S., has been [illegible] Health for Holsworthy (Devon) [illegible]

[illegible], D.P.H., has been appointed Lecturer on [illegible] the Glasgow Royal Infirmary.

[illegible] L Edin., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Ophthalmic Surgeon to the Hull Royal Infirmary.

MOLE, H. F., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon to the Royal Infirmary, Bristol.

SCALES, F. SHILLINGTON, B.C. Cantab., has been appointed Honorary Medical Officer in Charge of the Electrical Department at Addenbrooke's Hospital, Cambridge.

WA[illegible] L.R.C.P. Lond., has been [illegible] [illegible]al Infirmary, Bristol.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEDFORD COUNTY HOSPITAL.—House Physician. Salary £60 per [illegible] [illegible]shing.

BIR[illegible] [illegible]OSPITAL, Woodchurch-road, [illegible] Officer.

BRE[illegible] [illegible]SYLUM.—Assistant Medical Officer. Salary £150 per annum, with board.

BRISTOL, BRENTRY CERTIFIED INEBRIATE REFORMATORY, Westbury-on-Trym.—Superintendent and Medical Officer. Salary £400 per annum, with board and residence.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—Assistant House Surgeon, unmarried. Salary £70 per annum, with board and lodging.

CARLISLE, CUMBERLAND INFIRMARY. [illegible] at rate of £80 and £100 per annum [illegible]

[illegible] Medical [illegible] £50 per [illegible]

EBBW VALE STEEL, IRON, AND COAL CO., LIMITED.—Medical Officer for the Inspection of Injured Workmen. Salary £250 per annum.

ECCLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £60 per annum, with board and washing.

EVELINA [illegible] Southwark Bridge-road, S.E.—Hous[illegible] [illegible]lary at rate of £60 per annum, with [illegible]

FULHAM [illegible] [illegible]ammersmith, W.—Assistant Medic[illegible] [illegible]alary £150 per annum, with board, [illegible]

GLASGOW, [illegible] SCHOOL.—Chair of Physiology.

HALIFAX, ROYAL HALIFAX INFIRMARY.—Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.

LEEDS, HOSPITAL FOR WOMEN AND CHILDREN.—Honorary Assistant Surgeon.

LIV[illegible] HOSPITAL.—Two House Physicians and [illegible] six months. Salary at rate of £60 per [illegible] [illegible]dence.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Resident Medical Officer, [illegible] 250.

MANCHEST[illegible] WOMEN AND CHILDREN, Park-place, [illegible] Surgeon. Salary £80 per annum, [illegible]

MANCHEST[illegible] [illegible]R WOMEN AND CHILDREN.—House [illegible] 50 per annum, with board and residence.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer at Hampstead, also Assistant Resident Medical Officer at Northwood. Salary in each case £50 per annum, with board and residence.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NORWICH, [illegible] PRIVATE ASYLUM.—Assistant Medical Officer. [illegible] found.

NORWICH, [illegible] HOSPITAL.—House Physician, unmarri[illegible] [illegible]m, with board, lodging, and [illegible]

[illegible]—Two Assistant Resident Surgeons, [illegible]ith apartments, attendance, light, and fuel.

OLDHAM INFIRMARY.—Senior House Surgeon, also Third House Surgeon, both for six months. Salary of former £120 per annum, and of latter £80 per annum, with residence, board, and laundry.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—House Surgeon, also Junior House Surgeon, both for six months, and unmarried. Salary of former at rate of £80 per annum, and of latter at rate of £40 per annum, with board, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—[illegible] for four months. Salary at rate [illegible] [illegible]dence, and washing.

QU[illegible] [illegible]ckney-road, Bethnal Green, E.—[illegible] £100 per annum, with board, residence, and washing.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

SUNDERLAND AND DURHAM COUNTY EYE INFIRMARY, Sunderland.—House Surgeon, unmarried. Salary £210 per annum.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

[illegible] STAFFORDSHIRE GENERAL HOSPITAL.—House [illegible] rate of £80 per annum, with board, lodging, [illegible] Resident Surgical Officer. Salary £125 per annum, with board, lodging, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

BOXALL.—On August 13th, at Rudgwick, Sussex, the wife of Frank Boxall, M.R.C.S., L.R.C.P., of a daughter.

EWENS.—On August 14th, at West Chase, Maldon, Essex, the wife of H. L. Ewens, M.D., of a daughter.

GOLDIE-SCOT.—On August 16th, at Pilmuir, Pencaitland, the wife of T. Goldie Scot, M.B., of a son.

MARRIAGES.

BABER—VINCENT-WING.—On August 12th, at St. Mary's Church, Wimbledon Park, Henry Aitkens Baber, M.R.C.S., L.S.A., to Ada Mary Vincent-Wing, of Hartley House, Chipping Sodbury, Glos.

DEATHS.

DAVIS.—On August 11th, at Walton-in-Gordano, Clevedon, Somerset, Theodore Davis, M.D. Lond., F.R.C.S. Eng., aged 75 years.

MENNIE.—On August 16th, suddenly, at Balgownie, 211, Bridge-road, Battersea, S.W., James Edward Mennie, M.B., Ch.B. Aberdeen.

STEELE-PERKINS.—On July 30th, at his residence, Wilton-place, Exeter, E. B. Steele-Perkins, L.S.A., in his 68th year.

N.B.—A fee of 5s. is c[illegible] *Births,*

Notes, Short Comments, and Answers to Correspondents.

THE TREATMENT OF ADDER BITES.

MEDICAL attention in this country has been recently directed towards the treatment of adder bites owing to the severe injury sustained from an English adder by Dr. Herbert Peck, medical officer of health of Chesterfield, an accident which happily has not been fraught with such serious results as appeared possible from the reports first published. A medical correspondent whose family is proceeding for a holiday to a Cumberland dale which is said to harbour a number of adders has written to us to inquire whether a serum can be obtained in this country to counteract their poison and what other means of treatment are available. We are not aware that a special antiveneno is prepared against *Vipera berus*, the English adder, but we gather from the excellent work on "Venoms" by Dr. Calmette of Lille that the anti-neurotoxic serum prepared from cobra venom may be partially effective against viperine venoms. *If, however, the particular venom contains much* of the poison known as hæmorrhagin that serum is apparently of little use. Dr. Calmette has found it impossible to procure sufficient quantities of venoms of various origins to furnish each country with the polyvalent serums corresponding to its particular needs, and it could hardly be expected that serums should have been prepared against the poisonous snakes of the temperate European countries, injuries from which are comparatively rare. The following is a brief abstract of Dr. Calmette's recommendations for the treatment of the bite of a venomous snake:—1. Prevent abso[illegible] not more than h[illegible] tively done if a [illegible] of the limb. 2 Wash the wound freely with fresh 2 per cent. solution of hypochlorite of lime, or 1 in 1000 solution of chloride of gold; if these are unavailable use a 1 per cent. solution of permanganate of potash. A few cubic centimetres of one of these reagents should be injected all round the bite punctures. 3. Cover the wound with a dressing damped with hypochlorite of lime or pure alcohol. 4. Administer serum *if available into the loose tissues of the abdominal wall* with a Pravatz syringe. If serious intoxication has supervened from 10 to 20 cubic centimetres may be injected into a vein. 5. Give copious hot drinks, tea or coffee, and induce perspiration by wrapping the patient in blankets. Dr. Calmette says that ammonia, alcohol, or morphine are useless, and strychnine may be actually harmful. Whilst this advice is probably the most authoritative that can be [illegible] place their chief reliance in [illegible] ifying the skin about the bite [illegible] ubbing in crystals of per- [illegible]

THE ETYMOLOGY OF "ALCOHOL."

To the Editor of THE LANCET.

SIR,—A recent article in a daily newspaper in discussing the etymology of the word alcohol stated it to be the Arabic *al kohl*; [illegible] entirely to itself." This interesting statement contains a certain portion of etymological and physical truth, but by no means the whole. A supplemental physical and physiological fact is that the Arabian beauties—and even the more well-to-do members of the coarser sex—used the kohl (or antimonial) black powder as an eyelid stain with a utilitarian object comparable to that which inspired the construction of the "Venetian blind"; it [illegible] burning for centuries the light of science for the gradual illumination of Western Europe. Chemistry, as well as algebra and arithmetic—inclusive of the 10 symbolic "digits" of the latter—emanated from the impenetrable deserts which have ever been so jealously guarded by the sons of Ishmael. And so little was its jargon understood in these Western isles of our own that a sixteenth century English version of the principal works of Geber, one of the fathers of "al"-chymy, was believed by the great Dr. Samuel Johnson to have suggested the invention of the new word "gibberish." (It is very evident, indeed, to the skilled reader that the translation had not been made by a scientific expert—or even by a literary artist.) Then the Arabs—with their Jewish neighbours—were the apostles of medicine to Western Europe The famous *Canon* of the Arabian [illegible] Europe for about five centuries. Th[illegible] came from "Araby" and adjacent l[illegible] chemical substances was always tested on the human body, when the novelty was observed to be a powerful reagent. It was soon found that a fairly dilute alcohol was one of the best of astringent and tonic *collyria*. Hence it was used as an *adjuvant* to *kohl*, and frequently as a *substitute*. Hence the etymology of alcohol. I may add that the cosmopolitan diffusion of therapeutic ideas which have long ceased to be orthodox is illustrated by a story of its use in a remote Irish dispensary three quarters of a century or so ago. Brandy was dispensed to a case of granular conjunctivitis, with instructions for use after addition of an equal bulk of water. The patient's wife was well to the front with the empty "medicine bottle" on the next dispensary day. The medical man, in pouring out a new supply of the collyrium, asked how the patient found the medicine to "agree" "Oh, he likes it greatly, yer honour," was the prompt reply, "but he can never get it any higher than his mouth."

I am, Sir, yours faithfully,

Dublin, July 28th, 1909. JOHN KNOTT, M.D. Dub.

THE HOSPITAL GAZETTES.

T[illegible] much to the fancy of the surrounding Bob Sawyers. We believe that [illegible] his [illegible] the [illegible] it off leaving the door open, the patient of course being unconscious. Thereupon the cat came in and ate the eye on the table The [illegible]

—The Clinical Supplement of the *London Hospital Gazette* for July is devoted to the "Surgical Aspects of Osteo arthritis," and is from the pen of Mr. H. E. Ridewood, whilst in the body of the paper is a clinical lecture on Diseases of the Gall-bladder by Mr. Frederic Eve, besides a de[illegible] The account of the London Hospital [illegible] Mr. A. C. A HOLIDAY HANDBOOK.

Mr. Walter Hill has issued a useful shilling guide book entitled, "The Holidays: Where to Stay and *What to See*," *to the districts* on the line of route of the Midland, London and North-Western, Great Northern, Great Eastern, Great Western, and *Great Central* Railway companies, and gives much useful information respecting the various towns served by these companies for the holiday-maker and tourist. There are lists of seaside, farmhouse, and country lodgings, with brief references to the *features of interest in their neighbourhoods*. The various maps and *illustrations with which the text of the* book is illustrated enhance its value to those fortunate people who have not yet taken their holidays and are making up their minds where to go for them.

THE FLY NUISANCE.

To the Editor of THE LANCET.

SIR,—I have been somewhat disappointed in the results of the formalin treatment mentioned in your columns a few weeks ago and should like to mention the method I employ in dealing with flies.

I use one of the ordinary dome-shaped fly bottles and the solution employed is simply the liquid paraffin of the Pharmacopœia, which has the advantage of being inodorous and (except to the insect community) non-poisonous. The addition of a few drops of oil of cloves prevents putrefaction of the dead flies and keeps the solution free from any objectionable smell which might otherwise arise. The mixture, however, does not seem to possess any particular attraction for flies; and this might appear at first sight a disadvantage, as it is usually necessary to "first catch your fly" by cautiously lowering the bottle over him. But this is where the sporting instincts are aroused and any hard-worked or impecunious practitioner who finds it impossible to go grouse shooting on the moors can (as I am doing) turn his attention to the smaller game of the tea-table, and thus obtain recreation which has certainly the merit of cheapness to recommend it, and which (like some advertised modes of increasing one's income) can be carried on "without interference of business." On a hot afternoon, with an hour to spare, the "bag" will be most encouraging. Once a fly touches the greasy solution he never gets out again, but slides down into it, and very quickly his career is terminated in what appears to be a comparatively comfortable state of asphyxia.

To be thus suddenly provided with a rapid and comfortable death whilst in the midst of a hearty meal must from the fly's point of view be a decided improvement on the ordinary fate of his fellows.

I am, Sir, yours faithfully,

London, August 10th, 1909. IN TOWN ALL AUGUST.

*** The majority of our correspondents have found the formaldehyde method very efficacious. It might be stated, however, that the addition has been mentioned of a teaspoonful of a sweet wine, e.g., port, or of spirit, e.g., whisky, to the formaldehyde, which appears to increase the attraction of the fluid for flies.—ED. L.

AN EXTRAORDINARY "TYPHOID CARRIER."

IN a recent editorial article in the *Boston Medical and Surgical Journal* "the most remarkable case of a typhoid bacillus carrier on record" was described. The subject was an Irish cook who had been detained two years at the hospital on the North Brother Island by the Health Department. It seemed necessary that she should be quarantined indefinitely as her release would be a menace to the health of the community. Frequent examinations showed that typhoid bacilli were constantly present in her system, and careful studies by Dr. George A. Soper and others seemed to indicate that they were generated in the gall-bladder and thence disseminated. Repeated experiments were made in order to find some method of stopping the development of the bacilli without success. It was seven years since the woman first came under observation. Twenty-six cases of typhoid fever had been traced to her with certainty and the total number of cases to which she had given rise was probably very large. The outbreaks of which she was the cause occurred in suburban well-to-do families in which she was employed as cook. She had never shown any signs of enteric fever.

COMPRESSED-AIR ILLNESS.

NOTWITHSTANDING the experience which has been acquired with reference to the action of compressed air on the human body, accidents continue to be reported from time to time. The *Engineer* of August 6th mentions that during the month of July several men were taken ill while working under a pressure of six atmospheres beneath the river Elbe. They all recovered and returned to work, but one of them, an engineer, again collapsed on subjecting himself to the increased atmospheric pressure, and died soon after being carried out.

A CURIOUS CASE.

To the Editor of THE LANCET.

SIR,—A collier, aged 20 years, was pushing a tub of coal before him where the roof of the pit is very low. A stone projecting from the roof scratched his back, causing some abrasions of the skin with slight bleeding in a few places. The roof of the pit is wet and foul water drops from it. On the fifth day after the accident I saw the case. The skin all along the dorsal vertebræ and horizontally to an extent of about seven inches was covered with inflamed papules. Two days after that these had become pustules and I punctured 30 or 40 of them. As he could not afford to run up a doctor's bill he got an order for admission into the infirmary from the parish medical officer, who glanced at his back and then signed the usual form for admission to the infirmary. That was on the eighth day from the accident. In about three weeks from the date of the accident the collier was practically well. He sued for compensation under the Employers' Liability Act. The medical referee from the company called on him for the first time 16 days after the accident and reported to the colliery company that it was not an accident but a case of acne vulgaris. The case came before the county court judge and the medical referee testified that it was a case of acne and that he must have been suffering from it for some time previously. The parish medical officer who saw him only for a moment or so, when filling the form for admission to the infirmary, on the eighth day of the accident, also testified that the case was one of acne vulgaris, and that he had seen the "typical blackheads." He also stated that acne was caused by dirt, "because these people don't wash themselves." He also stated that he had had five or six acne cases in his own practice among colliers. Judgment was given for the defendant. I may state here that another coll[illegible] who was close at hand saw the accident and gave evidence as to what happened before the court.

The collier is a healthy man with a beautifully clean skin. There was not a single pimple on head, face, neck, or chest, or anywhere except on the back, and his father says there was not a single pimple on his son's back before the accident. My theory is that it was a case of artificial acne, the irritant being the dirty water acting on the chafed or abraded skin, and the dirty water was kept in contact with his skin by his wet shirt.

Is it correct to say that blackheads are "typical" of acne vulgaris, supposing that these were present and that no mistake has been made here?

I am, Sir, yours faithfully,

August 2nd, 1909. O. O'H.

*** This case does not appear to be a typical case of acne vulgaris from its history. A possible diagnosis is septic folliculitis, if it is not, as our correspondent suggests, an artificial acne. But the data are not sufficient to form grounds for a diagnosis.—ED. L.

DR. BARNARDO'S HOMES.

THE forty-third annual report of Dr. Barnardo's Homes for the 1908 has just been issued in the form of a 64-page pamphlet wi appropriate coloured wrapper containing a number of pictures trative of the work of the institution. The number of orpha destitute children rescued in 43 years has been 67,634. Last 2518 children were admitted. The death-rate among the chi boarded out in rural districts was 2·75 per 1000, while the deat covering all the homes was about 9·24 per 1000. On admissio per cent. of the children showed signs of tuberculosis and 3 cent. of the deaths in the homes were due to tuberculosis. stated that over 12 per cent. of all cases treated in hospital s from tuberculous disease in some form. It should be rememb that a large number of the children who come under the care o institution belong to the defective or incurable class. A tab zymotic diseases shows that 41 children suffered from scarlet with 2 deaths, 120 from measles with 3 deaths, 54 from Ge measles with no deaths, 60 from whooping-cough with 2 de 11 from diphtheria with 4 deaths, 4 from enteric fever with 1 d 54 from chicken-pox with no deaths, 34 from mumps with no de making a total of 378 cases with 12 deaths. Copies of the report be obtained, post free for six stamps, on application to the h quarters of the Homes, 18 to 26, Stepney-causeway, London, E.

◆

Old School.—We agree with our correspondent in some of his strict on the letter sent out by a candidate for a vacant medical post, that letter is by no means a particularly bad specimen of its class. think that the method adopted of forbidding all canvassing an limiting the number of testimonials to three or so should be n regularly adopted.

Library.—We could not give an estimate of the value of the b without seeing its condition and title-page, but such seventeen century tracts are not, as a rule, worth more than a few shillings. our correspondent refers to recent numbers of "*Book Prices Curren* he may see the work in question quoted if it has a saleable value.

Enamel.—According to our analysis, the preparation is qui innocuous, consisting of shellac, wax, and plaster-of-Paris. It co tains no poisonous metal.

COMMUNICATIONS not noticed in our present issue will receive attent in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed *olusively* "TO THE EDITOR," and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention should e given to this notice.

is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

ectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

etters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

'e cannot prescribe or recommend practitioners.

ocal papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

etters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

'e cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1909, which was completed with e issue of June 26th, and the Title-page to the volume, ere given in THE LANCET of July 3rd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1909.

An Address to Students.

It has for long been the custom of The Lancet to devote a number at this period of the year to a description of the facilities for medical education in the United Kingdom, and although we may thereby forestall the opening addresses that will be delivered in many of the medical schools during the first days of October, it still seems useful to us to fill the first columns of our Students' Number with a consideration of certain aspects of the current practice of medicine which have an interest for those who will shortly be entering upon its systematic study. With the October lecturers we have this in common, that our remarks are in no way concerned with the choice of medicine as a profession. That choice will have been made by the great *majority of those who turn to these pages for guidance*, and whether they have chosen ill or well rests to some extent, perhaps, on their future chances, but in the chief degree upon the five or six years that lie next before them.

There is a story of a bluff and outspoken surgeon who occupied the platform at the inaugural ceremony of the medical school year nearly a century ago, and whose first answer to the applause which greeted his appearance before the well-packed benches was an unexpected "Good heavens, gentlemen, what is to become of you all!" Not even a professional curmudgeon would bestow so cynical a greeting upon a body of medical students of to-day, for despite the traditional hardness of the medical man's life, it is true to say that given good health, industry, an ordinary self-discipline, and a facility for social intercourse—a quality by no means to be neglected during student life—a practitioner who has passed through the modern curriculum of medical education has capitalised the expenses which it has entailed into a well-assured means of earning a decent living. If he has during that period developed to a pronounced degree certain scientific or technical or personal attainments he has a fair prospect of making a very good living, even though his expenses will become larger in proportion to his income. But although we feel justified in pronouncing a fairly cheerful prognosis for the prospects of the average student, we are far from declaring that everything is for the best in this best of all possible medical worlds. There are, on the contrary, several severe disabilities which have to be faced in the practice of medicine in this country, and our present intention is to forewarn a certain number of its future practitioners of the most flagrant of these abuses at the outset of their connexion with their profession. We do this, as it seems to us that the best hope of mitigating the evil lies in the continuous increase in the professional efficiency of the men and women who will in the future be admitted to the practice of the medical profession by the qualifying bodies of the United Kingdom. The beginning of the cure, in fact, rests in the hands of the present generation of students, and the disease which they will have to face is, we suppose, as universal as human nature in its distribution.

Unqualified practice—the deliberate attempt of those who have not been taught at usurping the position of those who have—constitutes an opposition which the practitioner has to face to-day in more virulent form than ever. It manifests itself in many ways. The most widespread of these is the patent-medicine bottle or pill-box, the contents of which range from substances as innocuous as they are useless to drugs of acknowledged and often dangerous potency. A very large proportion of people in this and in every other nation is in the habit of buying these products from vendors in whom a keen and rapacious business ability replaces any approved medical knowledge, and under the direction of a printed label the purchasers continue to dose themselves for weeks or months at a stretch for diseases with which, aided much by the suggestive influence of the advertisements in newspapers that brought the nostrum to their notice, they imagine themselves to be afflicted. The maker and advertiser of the nostrum and the patient who considers himself competent to diagnose his *own condition* and to prescribe his own remedy form but too often an ideal conjunction of knave and fool. Again, a person, not rarely a person ignorant out of the common, announces a method of curing some special ailment, frequently cancer, consumption, asthma, paralysis, dislocations, or corns. This Cagliostro pushes his claims (which are beyond all the boasts of orthodox medicine) by means of advertisements and on the stage of assembly halls, with the result that the public is gulled into parting with its money in return for a limited amount of frequently injurious treatment. The drugs or manipulations which the quack administers may not always be actively harmful, but indirectly they all may have fatal results by giving a false sense of security to a patient whom skilful, prompt, and drastic measures can alone save. Such a case is that of a woman with a cancerous growth in her breast who buys and rubs into it an irritant ointment and persists in neglecting the only advice which would have directed her to proper treatment until her disease has spread beyond the surgical aid that might well have been effective at the outset. In such a case it is true the quack may be brought to book in the law courts if he has definitely promised a cure, but if he has not, and provided he has assumed no medical title or qualification, the law allows him to pursue his truly nefarious trade without hindrance. The law says so implicitly if not explicitly, for the preamble of the Medical Act of 1858, which established the Register of qualified medical practitioners, runs: "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners," which clearly gives the public the equal chance of picking or avoiding either class. And we have not yet exhausted the list of medically ignorant persons who are allowed to take advantage of the blindness of the public where its physical welfare is concerned. "Faith-healers," under the titles of Christian Scientists, Mental Healers, and the like, employ a combination

No. 4487.

of "suggestion" treatment—a treatment by no means to be despised under proper scientific control—with doctrinal formulæ as a system for the cure of disease and for the gain of personal emoluments or notoriety. As in the case of the blatant quacks of whom we have spoken, these mystical practitioners constitute a danger to the public on account of their inability to differentiate between organic and functional disease which leads them to promise a false security to their patients. A prominent section of them denies the existence of disease except in the mind of the patient, and is able apparently to convince of the sense of their teaching not only the sick people but their healthy relatives.

The attitude of the persons who accept the pretensions of these various irregular practitioners may fairly be figured by that of a man with no knowledge of the sea owning a yacht in which he wishes to cross the ocean, and to whom a plausible longshoreman offers his services with the tale that he has a unique system of navigation by which the port of destination will be reached in half the time usually regarded as possible. Inquiries as to the source of his secret elicit no substantiation of his claims, but the yacht owner, apparently crediting him with a divine inspiration and imagining his services to be cheaper than those of a certificated master, puts him in charge of his vessel, only to come to grief on rock or sandbank. This seems to us an under-statement of the gullibility of those who to pilot them through sickness seek the services of one quite unfitted for the investigation of the symptoms of disease and unskilled in their interpretation. In almost every other branch of human activity save in the practice of medicine the public is content to credit men trained to a special calling with special aptness to follow that calling, and it seeks their aid when the special services in question are required. But medical advice and medical treatment—involving knowledge so multiform, so perplexing, and so exacting that five years of constant study can only barely fit a man to enter upon them—are sought by the public, the very people most interested in their skilful exercise, from the hands of persons with no further qualifications than an empirical half-knowledge backed by impudent assurances. This statement of fact can hardly fail to elicit the question, "If so large a section of the public neglect their own interest in this matter, is it not the duty of the State to protect them in spite of themselves, as it protects them from being victimised by other enemies of the people?" The reply is that whatever we may consider the duty of the State to be in the matter, such benevolent interference can hardly be reckoned within the sphere of practical politics. The right of every citizen to impair his physical efficiency under the misdirections of unqualified practitioners or to experiment upon his children's health by dosing them with patent medicines of the nature of which he is entirely ignorant appears to constitute an inalienable privilege of the liberty of the subject, and its total suppression can only be contemplated in the vision of Utopia. And wise men do not seek this sort of absolute protection for science which can so greatly rely upon its own strength, while they recognise the necessity of not interfering unduly with the discretion of the public and the ministration of friends. What is wanted, and wanted badly, however, is control of the quack, and this it seems possible we, in common with other civilised nations, may enjoy. We may hope that in the course of the near future some legislative steps will be taken towards this end; indeed, the General Medical Council is at present engaged in collecting evidence which may lead to the appointment of a Royal Commission to inquire into the whole matter. But between the uncertain report of a problematica commission and the enrichment of the Statute book with a measure of practical utility a great gulf of years may well be fixed, and even were such a measure enacted the coöperation of the nation would still be needful to give it full effect. A well-framed Act to regulate the licence of the charlatan and to suppress at any rate the more glaring evils of unqualified practice would meet with general approval, but we would urge upon the younger members of the medical profession, those who will supply its most active force during the next few decades, the necessity of facing the evil for themselves and not sitting down to wait for relief which the State may be tardy to give them. It is, indeed, good to impress legislators with the righteous claims of the trained and sworn defenders of the human body against freebooters; it is better still to educate the public into a just appreciation between the merits of the two camps. How is this to be done? We think only in one way. Personal argument and persuasiveness may appeal to the more intelligent section of the community now under thrall to the patent medicine vendor, but even some of these may fall away from their new-found faith when the medical adviser is not at hand to spoil the seduction of some lying advertisement. The real weapon must be increased medical efficiency, keeping pace with the intelligence of a public becoming more and more educated. The truth of medicine must be made plainer and plainer to the eyes of a vast number of persons who want to understand and whose desire should be satisfied.

Those who are entering upon the study of medicine owe it to themselves, to their calling, to their brethren, and to the public welfare to make their apprenticeship a time of laborious days—which will yet leave space for not a few reasonable delights—so that when the hour comes for them to pass out from the sympathetic shelter of their schools they may be equipped with so complete and ready a knowledge of the principles of medicine that in their hands its practice shall be thorough, resourceful, and honest, and will thus afford an impressive refutation of the claims of uneducated charlatans, however loud their pretensions to a knowledge of the healing art. As the efficiency of our science increases, so will its value become more manifest even to the careless eye; and men turning in increasing numbers to medicine for the fruits of knowledge will realise the falseness of the pretenders' promises. To this consummation we look forward with confidence; its achievement is for the future generations of the medical profession; whether it come early or late will depend on the profession itself, not only upon the work of its leaders, upon the renown of the teachers in its schools, the astounding triumphs of its surgeons, the patient researches of its pathologists, the enunciation of wide new principles by its most brilliant minds, but upon the great body of practitioners throughout the land, who will spread abroad the knowledge of all these and of many smaller things, who will apply their practical lessons to the restoration and preservation of health and the mitigation of pain, and who in so doing will add their own quota of observation and experience to the sum of scientific knowledge. This is no visionary picture; it is the inevitable outcome of a contemplation of the recent history of medicine and of collateral science. True, the followers of medicine have a harder task than those who profess the physical sciences, for all their researches are complicated, and too many are baffled, by the inscrutable problems of life and to a lesser degree of human personality; but such watchwords as antisepsis, anæsthesia, serum-therapy, vaccination, malarial prophylaxis, are sufficient to remind us of the victories which have been won within the space of a century over the primæval forces of disease and death. Are not these a splendid earnest for the future of medicine? And in spite of them all there are yet fields for conquest to glut the ambition of a very ALEXANDER of science: Cancer, Bright's disease, insanity, epilepsy, plague, acute rheumatism, sleeping sickness, tuberculosis—here are only a few of the enemies from which mankind must look to medicine for deliverance by prophylaxis or by cure. The field-marshal's baton in the soldier's knapsack was a bauble beside the future fame and gratitude that await the man who shall do the transcendent service to his race that is implied in the successful solution of any one of the remaining problems—a man perhaps now entering upon the studies that are to form the prelude for this grand performance. If any doubt the reward, let him remember that an extensive plebiscite of France placed PASTEUR above NAPOLEON as the greatest of Frenchmen.

And we repeat that in the accumulation of such victories and in the education of the public mind to their significance lie the destruction of unqualified practice. Its end will be not a violent but a "natural" death—a death from inanition. Too premature an attempt to kill it will meet with determined opposition from powerful forces of vested interests and finance. When it begins to languish in the growing light of the knowledge of scientific medicine, finance will soon enough leave it to its fate. But that light needs constant kindling by fresh torch-bearers if it is to burn with increasing brilliance. In the beginning all was dark; then arose the twilight of an empirical medicine which, though at first in priestly hands, later any man might learn by observation, aided by tradition. The Middle Ages knew a professional class of medical practitioners who sought to conceal the instability of the foundations of their art by adorning it with a windy and fantastic scholasticism. Perhaps in those times the unorthodox and untrained practitioner was often a better healer than the learned doctor, for he was untrammelled by such mental lumber, and he did not scorn to use his hands. And thus the quack gained his foothold in mediæval England. When BACON and HARVEY brought the experimental method into English medicine the empirical practitioner began to be hopelessly left behind in the march of medical science, and in mediæval ignorance he still remains. But the nation that took him to its heart in the ages of scientific darkness still clings to him and reads attentively in its newspapers the same glib lies as sounded through the market places of the fifteenth century. Many imperfections still remain in our system of orthodox medicine, imperfections which afford the quack of to-day the chief weapons in his armoury, his loud claims to success where "no doctor could give relief." But in spite of his claims it is noteworthy that his only effective remedies are borrowed from the orthodox pharmacopœias and that a large part of their benefit is often lost owing to the indiscriminate methods of their administration.

This, then, is the situation which every student now entering upon the medical curriculum will have to face when he has been registered as a person qualified for the practice of medicine. We do not wish to magnify the apparent disability that it will bring to any individual practitioner, for the amount of direct competition which each will meet from unqualified persons is small, and the self-drugging practised so universally by all classes leads ultimately to the accession of patients who have found out the folly of it. But a great number will go on dosing themselves year after year, suffering many things rather than applying for scientific advice, or will apply for that advice when medical services can no longer hold out any prospect of relief. Some of these unfortunate folk, it is true, continue to treat themselves because they "can't afford doctors" and will not apply for Poor-law relief, but this is a situation which impending legislation will probably alter. The problem of medical relief for the poor no less than for the destitute is a very difficult one, and the statutes will be hard to frame which are to meet all the complications. But legislation will be successful by as much as it attempts to reward adequately the medical man who has to do the work, and it behoves our profession to be ready to deserve generous treatment. It should be the aim of our profession to increase its own efficiency by every means in its power and to show the public the overwhelming preponderance of benefit due to its ministrations.

As to the means by which the individual student may best prepare himself for this task, if he attend the opening lecture at his school in October he will very likely hear excellent advice on the matter. We will only say that he will find himself face to face with an overloaded course of study and that he cannot afford to waste a day in sitting down to look at it If he passes through it in the statutory five years he will have done exceedingly well; there are experienced teachers who consider that the time is in all cases by a year too short for what he has to do and learn. The University of London has indeed recently given effect to this opinion by adding six months to the curriculum for its medical degrees, and it has also redistributed the time at the student's disposal by giving the period of clinical studies an advantage over that spent in the aquisition of the preliminary medical sciences. With this latter policy we are in full accord, for it concentrates the student's attention upon his life work—the study and treatment of sick people. To do this effectively we would advise him to learn as much as he can at the bedside and as little as need be from books. Books are, of course, necessary: while they are replacing largely the old formal lectures, which tend more and more to become conversational demonstrations, books bring the student into acquaintance with a large number of facts all of which he cannot have an opportunity to learn from personal observation but which it is necessary that he should master. But books have their dangers. Over a certain type of mind they have such an influence that its possessor will frequent the library in preference to the ward, and at examination, when confronted with the task of describing a disease, will not search his memory for the likeness of a case which he daily observed at the bedside but will attempt to conjure up a picture of a printed page, and to transfer its contents to paper. In our experience those qualified men who are now doing brilliant work in ward and laboratory have rarely been omnivorous crammers of other men's writings. If asked to supply a scheme for the allotment of the student's hours when he has entered upon his clinical work we should say, give most to the wards and special departments, give as much to the clinical laboratories and post-mortem room as to the study of books, and out of the remainder devoted to exercise on playing fields, drill-ground, or river, leave something for the cultivation of general literature and of the society of people not interested in medical matters and averse from their discussion.

Lastly, have an ideal, or fixed ambition. This is a very valuable equipment for every student. The ideal of the medical student need not be beyond the dreams of fulfilment, but it had better be beyond likelihood, for it will then last longer and command a deeper devotion. Scientific eminence, and even the universal fame of a LISTER or of a HUXLEY, may be the light which a few will follow; others, probably the majority, will be content with a humbler humanitarian aim. Though it is now not the mode to vaunt the nobility of the profession of medicine, but rather to allow that it is but a hard-working manner of earning a living, yet our calling remains the most humane, often the most unselfish, and perhaps the most interesting of all mortal activities. It is, moreover, a profession of growing consequence in the life of the nation and one to which the statesman, the general, and the civic authority must look with increasing respect for counsel and coöperation vital to the great interests under their keeping. The proper and full advancement of medicine rests with its practitioners, as does the only sound policy for the defeat of unqualified opponents; and splendid as is the scientific heritage of medical men in the United Kingdom, the labours of those who have gone before will avail them nothing unless their results are regularly added to by patient and continuous work. For work, we have it on the word of a master of medicine whom our country has delighted to honour, is the master-word in medicine.

AN ADDITIONAL DIRECT REPRESENTATIVE FOR THE GENERAL MEDICAL COUNCIL.—The *London Gazette* of August 20th announces that the King has approved of the Privy Council's recommendation that the registered medical practitioners in England and Wales shall have the power of returning an additional member to the General Council of Medical Education and Registration, but that the addition in question shall not be made until the next ensuing general election of Direct Representatives.

THE MEDICAL BRANCH OF THE OFFICERS TRAINING CORPS.

NO student can fail to have paid some attention to the reorganisation of our national defences which has taken place during Mr. Haldane's tenure of the War Office through the machinery of his Territorial Army scheme. Those who have followed its development more closely will be aware that the scheme has included what the old Volunteer forces sadly lacked—the establishment of an efficient medical and sanitary service for the Territorial Army upon a basis similar to the Royal Army Medical Corps which serves the expeditionary or "Regular" Forces. This scheme has been due in chief measure to the administrative ability and enthusiastic work of the late Director-General of the Army Medical Service, Surgeon-General Sir Alfred Keogh, who with his chief staff officers last year made a tour of the country, addressing large audiences of medical men in many important centres, explaining the details of his scheme and inviting them to discuss its details, with the result that he secured the sympathetic coöperation of the medical profession and the enrolment of a large number of its members as active or *à-la-suite* officers of the Territorial branch of the Royal Army Medical Corps. It is quite obvious that the upkeep of this most important branch of the military service of the country will always depend entirely upon the medical profession, and those who are entering upon their preparation for that calling may well consider what steps they can take to prepare themselves to take their part in the national defence. There are a certain number of medical men and students who are more attracted to the combatant side of the Territorial service, perhaps because it affords a complete change from their ordinary work, but the scientific services of a man possessed of medical knowledge must be, as a rule, of far more value to the army than could be his combatant services. In every recent large campaign the military medical services have had to be augmented by civil practitioners, and however skilful at their work these emergency volunteers may have been, it is obvious that they would have performed it under much easier conditions if they had undergone a thorough peace training in the practice of military medicine in the field The ordinary civil surgeon, for instance, is totally ignorant of the principles of camp sanitation, or of the hygienic control of troops on the march. We need say no more to urge students from the outset of their medical studies to begin to master the most useful methods by which they can place their expert knowledge at the disposal of their country in time of need, but we would call their attention to the fact that in the Medical Branch of the Officers Training Corps there exists the ideal means for such a patriotic self-preparation. The Officers Training Corps was founded last year to give a preliminary military training to undergraduates at the various universities and other students, and thus to prepare for the establishment of an efficient reserve of officers and to supply commissioned officers for the Territorial Army, thereby fulfilling a national need which was never adequately met under the old Volunteer system. It is now proposed to form in Officers Training Corps centres where there are medical schools Medical Training Units such as we have described, and such units have been already established at Oxford, Cambridge, Edinburgh, and London, the latter University having raised since January last about 230 medical cadets, who are now efficient for their first year. The raising of similar units in other university centres depends entirely upon the enthusiasm of their medical students, and even if the hospital cricket and football teams have to suffer in consequence, it is to be hoped that before very long every branch of the Officers Training Corps will have an efficient medical section. We must add that cadets of the Officers Training Corps have no legal liability to service, not having to take the oath of allegiance, but should they intend to join the Special Reserve of Officers, the Territorial Force, or the Royal Army Medical Corps, the possession of certificates "A" and "B" taken in the Officers Training Corps after two years' efficient service will give them special advantages in the reduction of their probationary periods, the exemption from certain promotion examinations, and the addition of marks to their credit in entrance examinations should they subsequently desire to enter the Royal Army Medical Corps. Further information can be obtained from the officers commanding the medical units of the Officers Training Corps at the centres we have mentioned, but it will be useful to print the following details of the training :—

The Training Unit which it is decided to form in the Medical Branch of the Officers Training Corps is a section of a field ambulance Its [illegible] a quartermaster, and about [illegible] complete field ambulance [illegible] the field ambulance is to [illegible] to the most advanced hos- [illegible] nication, and provide the [illegible] in their care. The unit [illegible] etchers and ambulance [illegible] yance of the wounded, [illegible] tents and medical and [illegible] r temporary housing and [illegible] personnel is similarly [illegible] a *personnel* of non com- [illegible] vers and bâtmen which in [illegible] Service Corps, forming a [illegible] rms an integral part of the field army in war, and there are three field ambulances to each infantry division. The field ambulance is under the immediate command of the medical branch, and is an autonomous and a self-contained unit. It offers opportunities of practising all the duties of the medical branch in the field The exercises that are practised in camp are—The laying out and pitching of the camp. The construction of field kitchens, &c. Bearer Division exercise. The rendering of first aid to, the collection and [illegible] Tent [illegible] an outfit consisting of a suit of service dress, forage cap, gaiters or puttees, and great-coat, subject to certain rules. The cost of the outfit will, in the case of cadets who obtain, or have already obtained, Certificate "A," be borne by army funds.

THE SIXTEENTH INTERNATIONAL MEDICAL CONGRESS AT BUDAPEST.—The following receptions and fêtes have been arranged during the approaching Congress. On August 28th a soirée of welcome will be given at 9 P.M. in the Gallery of Fine Arts. On the next day, at 11 A.M., the official opening of the Congress will take place at the municipal redoubt, and at 3 P.M. the inauguration of the statue of the late Professor Joseph de Fodor in Sándor-tér (Alexander-square). In the evening the President of the [illegible] Park Club in honour of the [illegible] ugust 30th, the municipality [illegible] an official reception to the congressists, and the next evening the ladies' soirée will take place. On Wednesday, Sept. 1st, at a Court evening reception, the Archduke Joseph, representing His Majesty the Emperor-King Francis Joseph, will receive the official delegates of the Governments, the University, and others. On Sept. 2nd the presidents of the 21 sections of the Congress will each give a reception, and on Sept. 3rd Count Albert Apponyi, Royal Hungarian Minister of Religion and Public Instruction, will give a final soirée at the Park Club Numerous invitations have been given to members of the Congress to visit scientific and other institutions in and near Budapest.

THE IMPERIAL CANCER RESEARCH FUND.—The honorary secretary of the Imperial Cancer Research Fund has received from the Duke of Bedford, vice-president, a further donation of £1000 towards meeting the overdraft at the bank, thus saving the Fund from drawing on its capital.

THE STUDENT'S GUIDE.

SESSION 1909-1910.

◆

A PREFATORY STATEMENT.

THE quantity of the subjects which fall necessarily within the scope of our educational number has now become very large, and it may be as well, as on previous occasions, to explain the scheme upon which the following guide to a medical career in this country is constructed.

The General Council of Medical Education and Registration, conveniently known as the General Medical Council, is the controlling authority, under the Privy Council, of the medical education of the land. Under the provisions of the Medical Acts various universities and corporations are recognised as being examining bodies whose degrees or diplomas entitle to medical registration, and it is among the duties of the General Medical Council to keep the official register and to ensure by periodical visitations that the tests of the various examining bodies are maintained at a due standard. We begin by describing the powers of the General Medical Council, and go on to give in detail the regulations of the various examining bodies.

But the student must be taught as well as examined, and the systems under which he can obtain instruction do not conform to one pattern. The curriculum of the medical student falls into two parts, the preliminary subjects and the professional subjects, and the two cannot be sharply divided. The extent to which they are allowed to overlap under different schemes of education varies a good deal, while the extent to which they ought to overlap is a perennial subject of debate. The important preliminary subjects are chemistry, pharmacology, physics, biology, anatomy, and physiology, and they are taught in the school proper; the professional subjects, medicine, surgery, and obstetric medicine—under which headings all forms of specialism are included—must be learned in the wards of a hospital. All schemes of medical education require a school and a hospital, but there their uniformity ends.

The first point on which the medical student has to make up his mind is whether he desires a medical degree which will give him the definite title of Doctor or Bachelor of Medicine (coupled in many cases with that of Bachelor of Surgery), or whether he will be content with a diploma certifying him to be a Member or Licentiate of one or other of the great medical corporations and as such entitled to be registered as a medical practitioner. If he desires a degree he must matriculate at a university and go through the course of studies required by the regulations of its medical faculty, and it is well that he should bear this in mind from the outset, for many diplomates. desiring later to becoming medical graduates, have been debarred from doing so through having neglected to pass a university matriculation examination at a time when they were freshly versed in their preliminary "arts" and general studies. It is particularly useful to take the London matriculation examination, which is accessible in several prominent centres, as it opens the door to the medical faculty of any British University. Accordingly we print with some detail the regulations for that standard, if much criticised, test of a good all-round secondary education.

In the Student's Guide to medical education, which follows, we have collected together under their respective headings the chief information concerning the facilities for medical study, both "preliminary" and "professional," and the regulations for examinations at the various teaching centres of the United Kingdom, so, for instance, that a student desiring to pursue his studies and obtain a medical degree at Cambridge, Edinburgh, or Manchester may find under one heading an account of the medical faculty of the University in question, of the hospitals which form its field for clinical instruction, and of the prizes and scholarships which it offers to the student of medicine.

It will be readily seen, however, that it is impossible to adhere rigidly to this plan without a good deal of overlapping and doubling of information, for, as is well known, the medical schools of some universities are served chiefly by hospitals in other centres. Thus the medical students of Oxford and Cambridge almost uniformly pursue their clinical studies in London, whilst any student who has gone through all his training in an approved provincial centre may sit for a degree in Medicine at London University. Again, when we come to consider the corporations which have the power to grant diplomas qualifying their possessors for the practice of medicine we find that they usually have no schools attached to them, but that they examine students who have gone through the curriculum at any recognised metropolitan or provincial school to the satisfaction of their teachers, and in accordance with the regulations of the corporations. The plan we have adopted has been to divide the Guide into the three main headings of England, Scotland, and Ireland, and to deal with medical education in each country as a separate entity, describing first the medical faculties of the universities in each country, and following with an account of the medical corporations having powers to grant diplomas by examination. Under the heading of each university we give a general description of its arrangements for conferring medical degrees, of its facilities for preparing its students for those degrees, particulars of its scholarships and prizes, and of the hospitals affording clinical instruction and situated in the neighbourhood of the university buildings. Following this plan, the metropolitan medical schools and hospitals are grouped in their proper place as schools of the University of London, although they serve other universities and the diploma-granting bodies. A similar plan is adopted in dealing with the provincial universities, the hospitals in connexion with each being described; for though these are not officially "schools" of the universities they supply an integral section of the teaching required by their candidates for medical graduation, and so for practical purposes may be looked on as constituent parts of the university system. The link is made all the closer by the common presence of many teachers on the medical staff of a hospital and on the staff of lecturers of the university with which that hospital is connected. Following the description of medical education at the universities, an account is given of the regulations of the various corporations granting diplomas for the practice of medicine. The schools serving these examining bodies are identical with those already described, with the addition of the principal colonial medical schools. The Student's Guide contains also an account of certain provincial hospitals which afford facilities for clinical instruction, and at which students may take out some part of their course, but which are not officially connected with any teaching centre.

Detailed information concerning all those medical schools and their hospitals naturally forms the bulk of the Students' Number of THE LANCET; but we follow upon this with an account of medical employment in the Naval, Military, and Indian Medical Services and in the Public Health Service. We add the chief information useful to those desiring a diploma in public health or a special training in tropical medicine, together with an account of the facilities for post-graduate study, a branch of medical education the importance of which is rightly receiving increasing recognition. The Student's Number concludes with a report upon the system of education in dental surgery.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

As there is apparently, even among members of the medical profession, a great amount of ignorance as to the powers and duties of the General Medical Council, we think it well to lay clearly before our readers what the General Medical Council is and also what it is not.

Many of the false ideas on the subject are due to the use of the shortened title, "General Medical Council." The full title is, "General Council of Medical Education and Registration of the United Kingdom." This title is in accordance with the Medical Act of 1858, by which the General Medical Council was established under the Privy Council to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. The Council was thus instituted not primarily for the benefit of the medical profession but to ensure an efficient medical service to the public. It is obvious that by so doing the profession itself gained, in that official sanction was given to reputable practitioners only, while a proper guarantee was afforded to the public that the standard of medical education should always keep abreast of the scientific knowledge of the day. The powers of the Council under which it fulfils these important functions fall under four heads. It is first a registering body: it registers the entry of students upon their medical studies and also the attainment by them of the degrees or other qualifications that legally entitle them to practise medicine. This last duty forms its chief service to the State, as a complete list of practitioners of legal standing is thus rendered available for the information of the public. Secondly, it assures the public that the education of medical men is kept up to an efficient standpoint by maintaining at the proper pitch the standard of the various medical examinations. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Here again it is the public interest that is first considered, although these powers are for the very material advantage of the medical profession. The last duty of the Council is the codification of pharmaceutical remedies. Reform in the administration of the finances of the Council has of recent years removed acute pecuniary strain from that body, but the day should soon come when the State, recognising the public value of the work of the Council, should be willing to subsidise its efforts. Registrars are appointed by the General Council and by the Branch Councils to keep registers of qualified persons. They are bound by Section XIV. of the Act to keep their registers correctly, a duty which, mainly owing to the apathy of members of the medical profession, can only be performed with difficulty.

It is as well here to put down the advantages, such as they are, of being duly registered. A duly registered practitioner may sue in the courts of law for the recovery of charges for medical attendance or advice, or surgical attendance or advice, or for the supply of medicine, or for the performance of any operation—provided that he is not debarred from suing by being a Fellow or a Member of any corporation which objects to its Fellows or Members so suing. He may be exempted, if he so desire, from serving on juries, from serving sundry corporate and parochial offices, and from serving in the Militia. Only a registered practitioner can hold appointments in the navy, army, and in sundry Poor-law and other institutions. Only a registered practitioner can sign a valid medical certificate. Removal of the name from the Register debars a man from all the above-mentioned privileges.

The General Medical Council is in no way a medical protection society or a medical defence union. It is not a professional union or a guild charged with looking after the interests of the medical profession after the manner of the old trades guilds, except in so far as it is concerned with the education of medical students. It has no powers over any member of the medical profession except to remove the name of any offending member from the roll of the profession or Medical Register. Practitioners may be removed from the Medical Register (1) if convicted of felony or misdemeanour in England, or in Ireland, or in

Scotland of any crime or offence, and (2) on being adjudged by the General Medical Council to have been guilty of "infamous conduct in a professional respect."

The General Medical Council is, we repeat, primarily a body charged with looking after medical education; it is but little concerned with medical politics and, as a matter of fact, the time of the Council is almost entirely taken up with considering educational and registration matters, the latter including the penal cases of removal from the Register. The Council at present consists of 34 members, of whom, as will be seen by the annexed list, all but 10 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and five others are elected by the members of the medical profession as Direct Representatives.

President of the General Council.—Sir Donald MacAlister, K.C.B. Members of the General Council.—Dr. Norman Moore, chosen by t[illegible] Sir Henry Morri[illegible] England; Sir Hug[illegible] Society of London [illegible] of Oxford; Sir [illegible] of Cambridge; [illegible] of Durham; D[illegible] Dr. John Dixon [illegible] Robert Saundby, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Alfred George Barrs, University of Leeds; and Dr. William Tusting Cocking, University of Sheffield. Sir John Batty Tuke, M.D., M.P., chosen by the Royal College of Physicians of Edinburgh; Dr. James William Beeman Hodsdon, Royal College of Surgeons of Edinburgh; Dr. David Neilson Knox, Faculty of Physicians and Surgeons of Glasgow; Sir Thomas Richard Fraser, M.D., University of Edinburgh; Sir Donald MacAlister, K.C.B., University of Glasgow; Dr. David White Finlay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore chosen by the Royal College of Physicians of Ireland; Sir Thomas Myles, Royal College of Surgeons in Ireland; Dr. Francis George Adye-Curran, Apothecaries' Hall of Ireland; Sir Charles Ball, University of Dublin; and Sir Christopher John Nixon, Bart., M.D., Royal University of Ireland. Nominated by His Majesty, with the advice of his Privy Council: Mr. Charles Sissmore Tomes, Sir William Henry Power, K.C.B., Sir John Williams, Bart., K.C.V.O., Dr. David Caldwell McVail, and Dr. James Little. Elected as Direct Representatives: Dr. Langley Browne, Dr. H. A. Latimer, Dr. L. S. McManus, Dr. Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Mr. Charles Sissmore Tomes and Sir Henry Morris, Bart.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration shall occupy at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Registration and Preliminary Examination of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medi[illegible] prescribed by [illegible] of medical stu[illegible] branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produc[illegible] cate of his hav[illegible] required by the [illegible] he has attained the age of 16 years, and has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each [illegible] several licensing [illegible] that part of the [illegible] sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are many institutions where medical study may be [illegible] tions are dealt [illegible] which reports [illegible]

The Preliminary Examination in General Education, required to be passed previously to registration as a medical student, is as follows:—

1. English language [illegible] including grammar, t[illegible] translation of Englis[illegible] prising (a) arithmetic [illegible] and (c) geometry, the [illegible] with easy deductions. [illegible] (b) a modern language.

In many cases the Council will not accept certificates of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been passed at the same time.

A degree in Arts of any university of the United Kingdom or of the colonies or a certificate of having passed the final examination for a degree in Arts or Science of any university in the United Kingdom is considered a sufficient testimonial of proficiency.

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 54, George-square, Edinburgh.—*Richard J. E. Roe, Registrar of the Branch Council for* Ireland, 35, Dawson-street, Dublin.

THE EXAMINING BODIES.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student.

I.—*Universities in the United Kingdom.*

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Responsions. Moderations.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination.

University of Durham.—Matriculation Examination for Science, Letters, and Music. Senior Local Examinations.

University of London.—Matriculation Examination.

Victoria University of Manchester.—Matriculation Examination.

University of Birmingham.—Matriculation Examination. Senior School-leaving Certificate.

University of Liverpool.—Matriculation Examination.

University of Leeds.—Matriculation Examination.

University of Wales.—Matriculation Examination.

University of Edinburgh.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science [illegible] reliminary Examination of the [illegible] Graduation in Arts or Science or Medicine and Surgery.

University of Glasgow.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery.

University of St. Andrews.—Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery. Final Examination for the diploma of L.L.A.

University of Dublin.—Junior Freshman Term Examination. Special Preliminary Examination. Junior Exhibition Examination. Examinations for the first, second, third, or fourth year in Arts.

The National University of Ireland: The Queen's University, Belfast.—The examinations of these newly constituted bodies are, of course, recognised by the Council.

Oxford and Cambridge Schools Examination Board.—Higher Certificate and School Examinations, Higher Certificate (certificates to include the required subjects).

II.—*Medical Licensing Bodies.*

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination.

III.—*Educational Bodies other than Universities.*

College of Preceptors.—Examination for a First Class Certificate; Preliminary Examination for Medical Students.

Intermediate Education Board of Ireland.—Middle Grade Examination; Senior Grade Examination.

Educational Institute of Scotland.—Preliminary Medical Examination.

Scottish Education Department.—Leaving Certificates in Higher Grade or in Honours. Intermediate Certificate.

Central Welsh Board.—Senior Certificate Examination.

IV.—*Indian, Colonial, and Foreign Universities and Colleges.*

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at one time; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language may be accepted instead of an Examination in Latin. The German Abiturienten-Examen of the Gymnasia and Real-gymnasia and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences are recognised by the General Medical Council.

The remainder of the curriculum, though all under the supervision of the Council, is in detail in the hands of the various degree- and diploma-granting bodies whose representatives are members of the General Medical Council. In the next pages we give the regulations of the various examining bodies, but it must always be remembered that the examinations are under the supervision of the General Medical Council who visit the various centres in turn and closely inspect the procedure.

THE MEDICAL EXAMINING BODIES AND SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS AVAILABLE IN THE BRITISH ISLANDS.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M. and D.M.*, and two degrees in Surgery, *B.Ch. and M.Ch.*

Graduates in Arts (B.A. or M.A.) are alone eligible for these degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy and Materia Medica with Pharmacy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics, and Chemistry, December and June; Animal Morphology, December and March; Botany, March and June; Professional (First and Second B.M.), June and December.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first, but Pathology and Hygiene may be taken before or with the remaining subjects. Before admission to the Second Examination candidates must present certificates of attendance on a course of laboratory instruction in Practical Pathology and Bacteriology and of having acted as post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also he must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The Regius Professor may direct the dissertation to be read in public. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed the M.Ch. examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

Travelling Fellowship, Scholarships, and Prizes.—The Public Health diplomas, being considered post-graduate, will be found in another column. A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. The stipend is paid by University College. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennally for research in some branch of medical science. The prize will be awarded in 1911. Candidates must send in their memoirs to the University Registry on or before Dec. 1st, 1908. No memoir for which any University prize has already been awarded is admitted to competition for the Radcliffe prize, and the prize will not be awarded more than once to the same candidate.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1902, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University (all of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science.

Professors—Anthropology: E. B. Tylor, M.A. Botany (Sherard): S. H. Vines, M.A. Chemistry (Waynflete): W. Odling, M.A. Comparative Anatomy (Linacre): G. C. Bourne, D.Sc. Human Anatomy: A. Thomson, M.A. Medicine (Regius): W. Osler, D.M., Hon. D.Sc. Natural Philosophy (Sedleian): A. E. H. Love, D.Sc. Physics (Wykeham): J. S. E. Townsend, M.A. Physiology (Waynflete): F. Gotch, M.A., D.Sc. Reader: J. S. Haldane, M.A. Zoology: E. B. Poulton, M.A., D.Sc. Pathology: G. Dreyer, M.D. Lecturer: E. W. A. Walker, D.M.

In addition to the University lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the B.A. degree.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. Pathological demonstrations are given in the post-mortem room at the Pathological Laboratory by the Professor of Pathology. Practical Pharmacy is taught in the Radcliffe Dispensary. Opportunities are offered to students who wish to act as surgical dressers and clinical clerks in the out-patient departments and in the wards. The Hospital contains 154 beds. Honorary Physician: Dr. E. B. Gray. Honorary Surgeon: Mr. A. Winkfield. Active Consulting Physician: Professor William Osler. Acting Staff:—Honorary Physicians: Dr. W. Tyrrell Brooks, Dr. W. Collier, and Dr. E. Mallam. Honorary Assistant Physician and Medical Registrar: Dr. A. Waters. Honorary Surgeons: Mr. Horatio P. Symonds, Mr. R. H. A. Whitelocke, and Mr. A. P. Parker. Honorary Assistant Surgeon and [illegible] vers. Consulting Oph- [illegible] Pathologist: Professor [illegible] l Surgeon: Mr. E. A. [illegible] Dr. R. H. Sankey. House Physician: Dr. G. Moore Johnson. House Surgeon: Mr. F. V. Milburn. Junior House Surgeon: Mr. M. B. Baines.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., which may, and should if possible, be done before coming into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A. or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine* (*M.B.*) five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second, and the first part of the third, examinations for M.B. Hospital practice and many of the requisite lectures may be attended in Cambridge, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection is abundant, and the laboratories for Pathology, Bacteriology, and Pharmacology are well equipped. Addenbrooke's Hospital provides for the necessary clinical training.

There are three examinations for M.B. The *first* includes Chemistry and other branches of Physics and Elementary Biology. These parts may be taken together or separately. The *second* includes Human Anatomy and Physiology. The *third* is divided into two parts—viz, (1) Pharmacology and General Pathology; (2) Principles and Practice of Surgery, Midwifery and Diseases Peculiar to Women, Principles and Practice of Physic. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed both parts of that examination are admitted to the registrable degree of *Bachelor of Surgery* (*B.C.*) without separate examination and without keeping an Act.

The degree of *Doctor of Medicine* (*M.D.*) may be taken three years after that of M.B. or four years after that of M.A. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *vivâ voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

For the degree of *Master of Surgery* (*M.C.*) the candidate must have passed all the examinations for B.C., or if he is an M.A. have obtained some other registrable qualification in surgery. He is required either (1) to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery, and to write an extempore essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B C. Before submitting original contributions he must have been qualified at least three years.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, Cambridge.

The Professors, Readers, and Lecturers in the various subjects are as follows. Professors—Anatomy: A. Macalister, M.D. Biology (Quick): G. H. F. Nuttall, Sc.D. Botany: A. C. Seward, M.A. Chemistry: W. J. Pope. Medicine (Downing): J. B. Bradbury, M.D. Natural Philosophy (Jacksonian): Sir James Dewar, M.A. Pathology: G. Sims Woodhead, M.A. Physic (Regius): T. Clifford Allbutt, M.D. Physiology: J. N. Langley, M.A. Surgery: F. H. Marsh, M.A. Zoology, &c.: A. Sedgwick, M.A. Readers—Botany: F. F. Blackman, M.A. Chemical Physiology: F. G. Hopkins, M.A., and A. E. Shipley, M.A. Lecturers—Physics: G. F. C. Searle, M.A., and C. T. R. Wilson, M.A. Botany: A. G. Tansley, M.A. Chemistry: Dr. Sell and Dr. Fenton. Organic Chemistry: S. Ruhemann, M.A. Advanced Morphology of Vertebrates: H. Gadow, M.A. Advanced Morphology of Invertebrates: A. E. Shipley, M A. Advanced Physiology: W. H. Gaskell, M.D., and L. E Shore, M.D. Physiology: H. K. Anderson, M.D. Physiological and Experimental Psychology: W. H. Rivers, M.A. Medical Jurisprudence: B. Anningson, M.D. Medicine: L. Humphry, M.D. Midwifery: A. C. Ingle, M.D. Surgery: G. E. Wherry, M.A., F.R C.S. Pathology (Huddersfield): T. S. P. Strangeways, M.A. Physiological Anthropology: W. L. H. Duckworth, M.D.

University Prize in Medicine.—There is only one University Prize in Medicine. The *Raymond Horton Smith Prize* (value £19) is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical Studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Deans.

Tropical Medicine and Hygiene.—Information on these subjects is given on p. 667 under the section on Public Health.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in the special methods of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit. The fee for pupilship is 3 guineas a term's course. Consulting Physician: Dr. P. W. Latham and Dr. D. MacAlister. Consulting Surgeon: Mr. G. Wallis. Physicians: Sir T. C. Allbutt, Dr. J. B. Bradbury, and Dr. L. Humphry. Assistant Physicians: Dr. E Lloyd Jones and Dr. J. A. Wright. Surgeons: Mr. G. Wallis, Mr. G. E. Wherry, Mr. F. Deighton, Mr. J. Griffiths, and Mr. F. H. Marsh. Assistant Surgeon: Mr. Cooke. Consulting Dental Surgeon: Mr. W. A. Rhodes. Dental Surgeons: Mr. A. Jones and Mr. C. F. Rumsey. Honorary Anæsthetists: Mr. G. S. Haynes and Mr. G. F. Rogers.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as a purely examining and degree conferring body with several affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament 1898 and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. It also appoints teachers in special subjects to give lectures at the University, and the question of a further centralisation of preliminary scientific studies has for some years occupied the very serious attention of the University and its constituent schools but is for the present in abeyance. A considerable sum of money was offered for the erection and equipment of an institute of medical sciences as a central school of the University, but unfortunately, as we think, a division of opinion in the Faculty of Medicine forced the University to abandon the project.

The medical degrees awarded by the University are those of M.D., M.S., and M.B., B.S., the two latter being now given together as a graduating degree, whereas formerly the M.B. alone was a qualifying degree and the B.S. was taken optionally as a separate examination. The medical degrees of the University of London are granted to both internal and external students, the former being students of the constituent schools and colleges of the University.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. Thus in the Faculty of Medicine, although there are at present no appointed teachers, there are 401 recognised teachers belonging to the various metropolitan medical schools. There are 212 recognised teachers in the Faculty of Science. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective medical schools.

Internal and External Students.—Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (*a*) under the direct control of the University or a committee appointed thereby, or in one or more of the schools of the University; or (*b*) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are University College Hospital, King's College Hospital, St. Bartholomew's Hospital, the London Hospital, Guy's Hospital, St. Thomas's Hospital, St. George's Hospital, the Middlesex Hospital, St. Mary's Hospital, Charing Cross Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students.

The Matriculation Examination—Students before being admitted to the University must either (1) have passed the Matriculation or the School Examination (Matriculation or Higher Standard), or (2) have been exempted therefrom under Statute 116 of the University which recognises certain other examinations in its lieu. Such exemption is granted to graduates of British and certain colonial universities, and under certain conditions to matriculated students of the Universities of Machester, Liverpool, Leeds, and Sheffield, to holders of the senior local certificates of the Universities of Oxford and Cambridge, the higher certificate of the Oxford and Cambridge Schools Examination Board, the Scotch school-leaving certificate, the senior grade certificate of the Intermediate Examination Board for Ireland, and to students who have passed their previous examination at Cambridge. The examinations for matriculation take place three times in each year—namely, on Sept. 15th (if that day be a Monday, or if not, on the Monday next preceding the 15th), on the second Monday in January, and on the second Monday in June (or July, as may be hereafter determined). The examinations in January and June (or July), but not that in September, may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies. (Neither Botany nor Drawing can be chosen for subjects in the Colonies.) It is noteworthy that the September examination affords an opportunity for prospective medical students who may have failed at the midsummer examination to pass the Matriculation in time to enter upon their medical course in October. Students who pass the January Matriculation are able to enter for the First Examination for Medical Degrees in the following July under certain conditions in the case of internal students. Every candidate must, on or before August 20th for the September examination, on or before Nov. 25th for the January examination, and on or before April 25th for the June (or July) examination, apply by postcard to the Principal for a form of entry, of which the first in order must be returned 14 days before the commencement of the September examination, the second on or before Dec. 1st, and the third on or before May 1st, accompanied in the same cover by a certificate showing that the candidate has completed his sixteenth year, and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, or a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate if of full age, will be accepted. As candidates cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Principal, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2. If he withdraws his name before the last day of entry it shall be returned to him. If he fails to present himself he shall be allowed to enter for a subsequent Matriculation within eight months on payment of £1. If he retires after the commencement of the examination or fails to pass it the full fee of £2 shall be payable on every re-entry. Candidates must show a competent knowledge of each of the following five subjects, according to the details specified: 1. English—Composition, Précis-writing, salient facts in English History and Geography. A subject for an essay, to be chosen by candidates, to test power of expression, thought, and arrangement and general knowledge. 2. Elementary Mathematics—Arithmetic, Algebra (including quadratic equations and graphs of simple functions), and the subjects of Euclid (Books I. to IV). 3. Latin, or Elementary Mechanics, or Elementary Physics (Heat, Light, and Sound), or Elementary Chemistry, or Elementary Botany. 4 and 5. Two of the following subjects, neither of which has been taken under Section 3 (if Latin be not taken, one of the other subjects must be another language from the list): Latin, Greek, French, German, Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced), Elementary Mechanics, Elementary Chemistry, Elementary Physics (Heat, Light, and Sound), Elementary Physics (Electricity and Magnetism), and Botany. Additional subjects, of which, however, candidates must give notice two months previous to the examination, are: Arabic, Sanskrit, Spanish, Portuguese, Italian, Hebrew, Chinese, Modern Dutch, and Zoology. A pass certificate signed by the Principal is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements. Besides the

University fee, a fee usually varying from £1 to £3 is charged by the local authorities and must be paid *at the local centre* immediately before the commencement of the several examinations.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), and the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*).

It is noteworthy that the curriculum for the medical degrees has recently been extended from five to five and a half years from the time of matriculation, except in the case of students who have passed the Preliminary Scientific Examination or the First Examination for Medical Degrees before July, 1910, and that the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees. Part II. of the former Preliminary Scientific Examination has now been made Part I. of the Second Examination.

A. *Internal Students.*—In order to be admitted to the Bachelor's degrees a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, and General Biology; (*b*) the Second Examination for Medical Degrees: Pa [illegible] Chemistry; Part II., Anatomy, [illegible] cology, including Pharmacy and [illegible] Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, including Therapeutics and Mental Diseases, Surgery, Midwifery and Diseases of Wom[illegible]

B. [illegible] Bachelor's degre[illegible] the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Professional Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more of the recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (*Inorganic Chemistry, Physics, and General Biology*) will take place twice in each year, commencing on the Monday following December 10th and on the second Monday in July. It must as a rule be passed by internal students not less than one academic year after matriculation and by external students not less than nine months after matriculation. Candidates, however, who have passed or been admitted under Statute 116 as exempt from matriculation in the preceding January will be admitted to the first examination for medical degrees in July as external students, or as internal students if they have attended the prescribed course of study throughout the session and obtained the consent of the authorities of their school or institution. Every candidate must apply (internal students to the academic registrar and external students to the external registrar) for a Form of Entry on or before Nov. 1st or May 24th, which must be returned, accompanied by the proper fee, not later than Nov. 8th for the December examination or June 1st for the July examination. The fee is £5 for each entry to the whole examination, provided that all the subjects are taken at one time. When less than the whole examination is taken at one time it is £2 for each subject. The examination will include two papers in each of the three subjects, three hours being allowed for each paper. Three hours each will be devoted to practical examinations in Inorganic Chemistry and Physics and six hours to a practical examination in General Biology. *Candidates must, at their first entry, present themselves in all three subjects.* Candidates failing in one subject only may, with permission, present themselves for re-examination in that subject on payment of the proper fee.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursdays following the third Monday in March and the second Monday in July. No candidate will be admitted to this examination within six months of having passed the First Examination. Every candidate must apply on or before Feb. 8th or May 24th for a form of entry, which must be returned not later than Feb. 15th for the March examination or June 1st for the July examination. The fee is £2 for the first and every subsequent entry. The examination will consist of a paper and practical work, and may include oral questions in Organic Chemistry, which is "to be treated in an elementary manner, and with special regard to its applications in physiology, pharmacology, and pathology."

The Second Examination for Medical Degrees (*Part II.*) takes place twice in every year, commencing on the third Monday in March and on the first Monday in July. The subjects of the examination are Human Anatomy and Embryology, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees. Internal students must have completed the courses of study prescribed for them by the University, and external students must produce certificates of having subsequently to having passed the First Examination for Medical Degrees been students during one and a half academic years at one or more of the medical institutions or schools recognised by the University and of having attended (1) a course of not less than 100 lectures and demonstrations on Human Anatomy; (2) a course of Dissections for not less than 12 months; (3) a course of not less than 60 lectures on Physiology; (4) adequate courses of Experimental Physiology, Histology, and Physiological Chemistry; (5) adequate courses of lectures and demonstrations on Pharmacology, Pharmacy, and Materia Medica; and (6) Practical Pharmacy for not less than two months. These certificates must be transmitted to the Registrar at least not later than Feb. 15th or June 1st for the March and July examinations respectively, applications for forms of entry having been made by Feb. 1st or May 17th. The fee for each entry to the whole examination is £8. For re-examination in one subject it is £4.

M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the last Monday in October and on the first Monday in May. No candidate except those who pass the Preliminary Science or First Examination for Medical Degrees before July, 1910, will be admitted to this examination within three academic years from the date of passing in Anatomy and Physiology at the Second Examination (Part II.), nor unless he has completed that examination together with prescribed courses of study or practice summarised below. (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Insanity (with clinical demonstrations at a recognised Asylum); (4) Therapeutics; (5) Vaccination; (6) Principles and P[illegible] Surgical Anatomy[illegible] of Anæsthetics; [illegible] (9) Lectures and Demonstrations on Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynæcological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a course of instruction at a recognised Fever Hospital for two months. He must have had clinical instruction and must have held the posts of medical clinical clerk and surgical dresser for periods of six months each. For internal students the above form the subjects of the last two and a half years of study as prescribed by the University. Forms of entry for the examination must be applied for on or before Sept. 21st or March 24th and returned with certificates of having undertaken the above-mentioned courses of study by Sept. 28th or April 1st respectively. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery and Diseases of Women. These groups may be taken either separately or together. The fee is £10 for each entry to the whole examination and £5 for examination or re-examination in either group. There will be no separate examination held for Honours, but the list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the degrees of M.B., B.S. not less than two years previously, but for those who have taken the M.B., B.S. degrees with honours or have done certain original work this period of delay may be reduced to one year. Candidates who have obtained their M.B. degrees in or before May, 1904, will not be required to hold the degree of B.S. before seeking the doctorate. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. In most branches an appointment at an approved hospital is necessary. Certain conditions have to be fulfilled in each case, varying according to the nature of the branch in question. Candidates who have passed or presented themselves for the M.D. examination in one branch may present themselves for examination in another branch at a subsequent examination. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from the written examination in that subject. The fee is £20, and for re-examination £10.

Note.—In and after the session 1910–11 with regard to the regulations for internal and external students in the Faculty of Medicine the following will apply. In Branches I. and IV. candidates (other than those who present a thesis) for the July examination must apply to the Academic or External Registrar for forms of entry on or before May 20th, which must be returned not later than June 1st, and candidates (other than those who present a thesis) for the December examination must apply for forms of entry on or before Oct. 20th, which must be returned not later than Nov. 1st. The corresponding dates for application for, and return of, forms of entry for candidates in Branches II., III., V., and VI., and candidates in other branches who present a thesis, are April 20th and May 1st for the July examination; and Sept. 20th and Oct. 1st for the December examination. Forms of entry must be returned duly filled up, accompanied by the proper fee, and by certificates, as enumerated below, for the branch concerned.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates must produce certificates of having taken the degrees of M.B. and B.S. not less than two years previously (with certain exemptions, as in the examination for the M.D.) and of having subsequently held for at least six months a resident or non-resident Surgical hospital appointment. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Surgery, Surgical Pathology and Anatomy, a Clinical examination, and operations on the dead body. Any candidate for the degree of M.S. may transmit to the Registrar, not later than two months before the commencement of the examination, a thesis or published work having definite relation to Surgery, and if the thesis be approved by the examiners the candidate may be exempted from the written examination in Surgery. The fee is £20, and for re-examination £10.

Full details of the prescribed curricula of study, with the syllabus for each examination and of certain exemptions which the Senate has power to grant in respect to certain examinations and the courses of study presented for them, and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. Students should apply direct to the University for this detailed information.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL.—The clinical practice of the hospital is large. The hospital contains 744 beds, of which 674 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley.

This hospital receives within its walls more than 7000 in-patients annually and its out-patients and casualties amount to more than 126,000 annually.

Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery in which Chief Assistants and Clinical Assistants are appointed annually. There is an Electrical Department, including X Ray, &c. Surgical operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. Medical Consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually. During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant of an ophthalmic house surgeon and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. All the appointments are now free. A residential college is attached to the hospital.

New Buildings.—The new buildings that have been recently opened comprise residential quarters for the resident staff, new casualty, medical, surgical, and special out-patient departments, new casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added, available for the Medical School, and affording facilities for instruction in Public Health. A second new Block which is devoted to Pathology, and contains extensive laboratories for bacteriology, clinical pathology, pathological histology, &c., was opened in May, 1909.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

Special Classes for the Final F.R.C.S. are held twice yearly.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. Additional rooms for the Students' Union have recently been added, viz.: (*a*) a large reading and smoking room; (*b*) a committee and writing room; and (*c*) luncheon and dining hall; and a miniature rifle range has been provided. These are in the new block.

Staff.—Consulting Physicians: Sir William S. Church, Bart., K.C.B., Dr. Hensley, Sir Lauder Brunton, Bart., F.R.S., Dr. Gee, and Sir Dyce Duckworth, Bart. Consulting Surgeons: Sir Thomas Smith, Bart., K.C.V.O., Mr. Willett,

---

[1] For Ancillary Metropolitan Medical Schools see p. 626.

Mr. Butlin, *Professor Marsh*, and Mr. Langton. Consulting Ophthalmic Surgeon: Mr. Henry Power. Consulting Aural Surgeon: Mr. Cumberbatch. Physicians: Dr. Norman Moore, Dr. Samuel West, Dr. Ormerod, Dr. Herringham, and Dr. Tooth, C.M.G. Surgeons: Mr. Harrison Cripps, Mr. Bruce Clarke, Mr. Anthony Bowlby, C.M.G., Mr. Lockwood, and Mr. D'Arcy Power. Assistant Physicians: Dr. Garrod, Dr. Calvert, Dr. Morley Fletcher, Dr. *Drysdale, and Dr. Horton-Smith-Hartley, M.V.O.* Assistant Surgeons: Mr. Waring, Mr. Eccles, Mr. Bailey, Mr. Rawling, and Mr. Gask. Physician Accoucheur: Dr. Champneys. Physician Accoucheur with charge of out-patients: Dr. W. S. A. Griffith. Surgeon to Obstetric Wards: Mr. Harrison Cripps. Assistant Physician Accoucheur: Dr. Williamson. Ophthalmic Surgeons: Mr. Jessop and Mr. Holmes Spicer. Surgeon, Throat and Nose Department: Mr. W. D. Harmer. Assistant Surgeon, Throat and Nose Department: Mr. F. A. Rose Aural Surgeon: Mr. Ernest West. Assistant Aural Surgeon: Mr. Sydney Scott. Dental Surgeons: Mr. Paterson and Mr. Ackland. Assistant Dental Surgeons: Dr. Austen and Mr. Coleman. Medical Officer in charge of Electrical Department: Dr. Lewis Jones. Assistant Medical Officer to Electrical Department: Dr. H. Walsham. Pathologist: Dr. Andrewes. Assistant Pathologist: Dr. H. M. Gordon. Administrators of Anæsthetics: Mr. Gill and Mr. Cross. Assistant Administrators of Anæsthetics: Mr. Boyle and Mr. Trewby. Medical Registrars: *Dr. Horder and Dr. Langdon Brown.* Surgical Registrar: Mr. Gordon Watson. Casualty Physicians: Dr. Haldin Davis and Dr. Woodwark.

Lectures and Demonstrations.—Medicine: Dr. Norman Moore and Dr. S. West. Clinical Medicine: Dr. Norman Moore, Dr. S. West, Dr. J. A. Ormerod, Dr. W. P. Herringham, and Dr. H. H. Tooth. Practical Medicine: Dr. J. H. Drysdale and Dr. Horton-Smith-Hartley. Surgery: Mr. W. Bruce Clarke and Mr. D'Arcy Power. Clinical Surgery: Mr. Harrison Cripps, Mr. W. Bruce Clarke, Mr. Anthony Bowlby, Mr. C. B. Lockwood, and Mr. D'Arcy Power. Practical Surgery: Mr. L. B. Rawling and Mr. G. E. Gask. Operative Surgery: Mr. W. McAdam Eccles, Mr. L. B. Rawling, and Mr. G. E. Gask. Midwifery and the Diseases of Women and Children: Dr. F. H. Champneys and Dr. W. S. A. Griffith. Practical Midwifery: Dr. J. D. Barris. Pathology: Dr. F. W. Andrewes. Bacteriology (advanced): Dr. E. E. Klein. Chemical Pathology: Dr. A. E. Garrod. Morbid Anatomy and Post Mortems: Dr. T. J. Horder, Dr. Langdon Brown, and Mr. Watson. Practical Pathology: Dr. H. Thursfield, Mr. R. C. Elmslie, Dr. Pritchard, *Mr. W. G. Ball, Mr. Jamison, and Mr. Walker.* Ophthalmic Medicine and Surgery: Mr. W. H. Jessop. *Diseases of the Eye: Mr. W. H. Jessop* and Mr. W. Holmes [illegible] Spicer. [illegible] Scott. [illegible] Mr. F. E. Rose. Orthopædic Surgery: Mr. W. McAdam Eccles. Diseases of the Skin: Dr. H. G. Adamson. Diseases of Children: *Dr. A. E. Garrod* and Dr. H. Morley Fletcher. Medical Electr[illegible] Dr. H. Lewis Jones and Dr. [illegible] Insanity: Dr. R. Jones. [illegible] and Mr. R. O. Ackland. [illegible] Cross, Mr. H. E. G. Bo[illegible] Medicine: Dr. W. P. Herringham. Descriptive and Surgical Anatomy: Dr. C. Addison. Practical Anatomy: Dr. C. Addison, Mr. R. B[illegible] and Mr. R. F. Moo[illegible] J. S. Edkins. Pra[illegible] W. L[illegible] [illegible]peutics: Dr. James Calvert. [illegible]idge. Biology and Comparative Anatomy: Dr. [illegible] Shore. Practical Biology: Dr. T. W. Shore and Dr. W. A. Cunnington. Chemistry: Dr. W. H. Hurtley. Practical Chemistry: Dr. W. H. Hurtley and Mr. K. S. Caldwell. Physics: Mr. F. Womack. Practical Physics: Mr. F. Womack and Mr. Lloyd Hopwood. Botany: Rev. G. Henslow. Public Health: Dr. George Newman. Sanitary Law: Dr. G. Newman and Dr. R. Porter. Museum Curator: Dr. F. W. Andrewes. Junior Curator: Dr. W. P. S. Branson. Dean of the School: Dr. T. W. Shore. Warden of College: Mr. G. E. Gask.

Scholarships given in aid of [illegible] various Scholarships, *prizes,* [illegible] the following list having a h[illegible] also other prizes and medals on a lower scale of value. For *five of the Scholarships and the Exhibition—namely,* (a), (b), (c), three Entrance Scholarships of the respective values of £75, £75, and £150; (d) Entrance Scholarship in Arts, £100; (e) Jeaffreson Exhibition, £50; and (f) Shuter Scholarship, *£50*—a *full* or University course at St. Bartholomew's Hospital is required. The awards of (a), (b), and (c) are made after examination in selections from the subjects of [illegible] and Anatom[illegible] Latin, Mat[illegible] is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. For the remaining Scholarships and prizes study at St. Bartholomew's Hospital is required. These remaining Scholarships and prizes, with the money value and the subjects of examination, are as follows:—Four Junior Scholarships: (g) No. 1, £30, Anatomy and Biology; (h) No. 2, £20, Anatomy and Biology; (i) No. 3, £25, Chemistry, Physics, and Histology; (j) No. 4, £15, Chemistry, Physics, and Histology; (k) Senior [illegible] and Chemistry; [illegible] Clinical Medicine; [illegible] £39 each, one i[illegible]rence Scholarship, £45 and medal, Surgery, Medicine, and Midwifery; (p) Sir Geo. Burro[illegible] (q) Skynner Prize, 13 guin[illegible] Anatomy; (r) Matthews Dun[illegible] Midwifery and Gynæcology; and (s) Luther Holden Research Scholarship in Surgery, awarded by election, £105.

CHARING CROSS HOSPITAL.—This hospital and convalescent home contain 200 beds, a certain proportion of which are set aside for the diseases of children and *those special to women.* The number of patients treated during 1908 amounted to 25,404—viz., 2178 in-patients and 23,226 out-patients, of [illegible] were 75,477 out-patient [illegible] appointments are open [illegible] *House Physicians,* six House Surgeons, and two Resident Obstetric Officers, appointed each year on the recommendation of the committee after competitive examinations, are provided with board and residence in the hospital. Clinical *clerks and dressers are appointed in all* the general and special departments of the hospital. Arrangements can be made *for students* who have not entered for the entire curriculum to hold these posts. In the medical school demonstratorships and assistant demonstratorships in various subjects are open to students of the school and carry honoraria. Total fees, including students' club:—For general students: 1. Composition fee, payable in one sum on joining, 115 guineas. 2 Sessional payment system: Entrance fee, 10 guineas. In addition a sum of *15 guineas* must be paid at the beginning of every Winter Session and one of 10 guineas at the beginning of every Summer Session so long as the student remains in the school. For Dental students: The fees for the two years' curriculum required by dental students may be paid: (a) in one sum of 55 guineas on entry; (b) in two instalments, one of 31 guineas on entry and the second of 30 guineas at the end of the first twelve months. General students pay proportionally lower fees and are admitted without additional fee to the courses of Clinical Medicine and Surgery. They are entitled to compete for the Scholarships which are awarded annually to the value of £500, including two University Scholarships, value 50 guineas and 40 guineas respectively, Gold Medal, Huxley, Livingstone, Travers, and Pereira Prizes.

Classes for the First and Second Examinations for Medical Degrees, Parts I. and II. of the University of London and for the Primary F.R.C.S. are held at this Medical School. There are *also special classes for the* practical work for the Department of Public Health and for the Primary F.R.C.S.

Staff.—Consulting Physicians: Dr. Green, Dr. Bruce, and Dr. Abercrombie. Consulting Obstetric Physician: Dr. J. Watt Blac[illegible] Dr. Mott, Dr. Galloway, and [illegible] Dr. Dr. Hunte[illegible] [illegible]lting Fenton, D[illegible] V.O. Surgeons: [illegible] Sur- Surgeons: [illegible] Mr. geon to Out-patients [illegible]

Clogg and Mr. Daniel. Obstetric Physician: Dr. Amand Routh. Obstetric Physician with care of Out-patients: Dr. T. W. Eden. Physician for Diseases of the Skin: Dr. Galloway. Assistant Physician for Diseases of the Skin: Dr. MacLeod. Physician to the Electrical Department: Dr. Ironside Bruce. Surgeon for Nose, Throat, and Ear: Mr. Waggett. Ophthalmic Surgeon: Mr. Treacher Collins. Orthopædic Surgeon: Mr. Fairbank. Surgeon Dentist: Mr. J. F. Colyer. Physician for Mental Diseases: Dr. Mercier.

Lecturers: Winter Session.—Anatomy: Dr. Alexander Macphail. Bacteriology: Mr. Leathem. Biology and Comparative Anatomy: Dr. H. W. Marett Tims. Chemistry and Physics: Dr. H. Forster Morley. Dental Surgery: Mr. J. F. Colyer. Medicine: Dr. James Galloway and Dr. F. W. Mott (Nervous Diseases). Ophthalmology: Mr. E. Treacher Collins. Physiology and Histology: Mr. O. F. Myers-Ward. Practical Anæsthetics: Mr. C. Carter Braine. Practical Anatomy: Dr. Alexander Macphail. Practical Hygiene: Mr. Leathem and Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Forsyth. Diseases of Women: Dr. Amand Routh and Dr. T. W. Eden. Practical Midwifery: Dr. T. W. Eden. Practical Physiology: Mr. O. F. Myers-Ward. Practical Surgery: Mr. F. C. Wallis, Mr. H. S. Clogg, Mr. Peter Daniel, and Mr. Fairbank. Operative Surgery: Mr. Charles Gibbs. Psychological Medicine: Dr. Mercier. Surgery: Mr. H. F. Waterhouse and Mr. F. C. Wallis. Tropical Medicine: Sir Patrick Manson, K.C M.G.

Summer Session.—Anatomy: Dr. Alexander Macphail. Anæsthetics: Mr. C. Carter Braine. Dental Surgery: Mr. J. F. Colyer. Forensic Medicine: Dr. Jewesbury. Materia Medica and Practical Pharmacy: Dr. Fenton. Midwifery: Dr. Amand Routh. Diseases of Women: Dr. Amand Routh and Dr. T. W. Eden. Pathology: Dr. W. Hunter. Pharmacology and Therapeutics: Dr. Fenton. Practical Chemistry: Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Forsyth. Practical Physiology: Mr. O. F. Myers-Ward. Public Health: Dr. H. T. Bulstrode. Toxicology: Dr. H. Forster Morley. Roentgen Ray: Dr. Ironside Bruce. Dean of the Medical School: Mr. Frederick C. Wallis.

Scholarships and Prizes.—At this school five Entrance Scholarships are awarded at the commencement of each Winter Session after examination in the following groups of subjects:—(1) English, including English Language and Literature, English History with alternative questions on the history of the British Empire, and Geography; (2) Latin and any one of the following three languages—Greek, French, and German; (3) Mathematics, including Arithmetic, Algebra, and Geometry: with Mechanics, including Statics and Dynamics; (4) Inorganic Chemistry and any three of the following branches of Experimental Physics—Acoustics, Heat, Magnetism, Electricity, and Optics; and (5) Animal and Vegetable Biology. A candidate may offer himself for examination in not more than three of the above groups of subjects, but Group (1) must be one of the three. The designations, money value, and conditions of the Entrance Scholarships are as follows:—(*a*) Livingstone, 75 guineas, open to all general students; (*b*) Huxley, 50 guineas, for sons of medical men; (*c*) 30 guineas, for dental students; (*d*) and (*e*), 30 and 20 guineas respectively, open to all general students. The remaining scholarships and prizes are as follows:—(*f*) Epsom Scholarship, open to Epsom Foundation Scholars who have passed the First Examination for Medical Degrees of the University of London (free education); (*g*) and (*h*) two Universities Scholarships awarded after examination in Anatomy and Physiology, including Histology, 50 and 40 guineas respectively; open to Oxford students who have passed the first M.B. Examination, or Cambridge students who have passed the second M.B. Examination, or London students who have passed the Intermediate Examination in Medicine and have not entered at any London Medical School; (*i*) Llewellyn Scholarship, awarded annually to the student of not more than five years' standing who has been most distinguished at the Prize Examinations in Medicine, Surgery, Midwifery, Pathology, Therapeutics, Forensic Medicine, Public Health, Psychological Medicine, Ophthalmology, and Practical Midwifery, £25; (*j*) Huxley Prize, awarded after Examination in Anatomy and Physiology at the end of the Second Winter Session, £3 3*s.*; (*k*) Golding Prize, awarded after competition among First-year Students in Anatomy and Physiology who have attended the classes in each subject at this school, £2 2*s.*; (*l*) Dr. T. H. Green Prize for Clinical Medicine, given annually for a special subject involving clinical observation in the wards or laboratory, 5 guineas; and (*m*) Dr. William Travers Prize for the student in the fifth year who is most proficient in Obstetrics and Gynæcology, £15. The Pereira Prize, £4 4*s.*, for the best reports with commentary on six cases that have been in the wards of the hospital during the preceding 12 months, for Students who have attended the clinical teaching of the Hospital for at least 12 months.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

The Winter Session commences on Oct. 1st but students can enter at any time or for any particular course. The Hospital and Medical School are situated at Hyde Park-corner and are readily accessible from all parts of London. Entrance Scholarships in Science and Arts and University Scholarships in Anatomy and Physiology are awarded at the commencement of each Winter Session. Prizes: The William Brown Exhibition of £100 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £40 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital. As the scientific and clinical parts of the medical student's curriculum are entirely separate there is no longer any object in conducting the scientific courses upon hospital premises. The entire teaching and laboratories are therefore now devoted to purely clinical subjects, as in other universities, to the great advantage of students in their fourth and fifth years of study. Arrangements have been made with the University of London for students who enter during the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at either University College or King's College. Students therefore have the unrivalled advantages of the lectures and practical classes of these Colleges of the University during the preliminary and intermediate portions of their studies, and then complete their course, without payment of any entrance fee, in a school entirely devoted to Clinical work. Students are permitted to enter the wards of the hospital at any hour. Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. Eight house physicians and eight house surgeons are appointed annually. All house appointments are open without fee to every perpetual student of the hospital and are made strictly in accordance with the merits of the candidates. Special attention is directed to the following paid appointments, amongst others, which are open to students after they have held house office:—Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Curatorship of the Museum at £200; Assistant Curatorship at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the post of Senior Anæsthetist at £50; the posts (2) of Junior Anæsthetists, each at £30. Great attention is paid by members of the staff to individual teaching. A number of special courses are given in which the requirements of university and other examinations receive careful attention. The following may be cited as examples:—(1) Elementary Bacteriology; (2) Advanced Bacteriology; (3) Clinical Pathology; (4) Systematic Pathology; (5) Histological Pathology and Morbid Anatomy; (6) Pharmacology; (7) Surgical Anatomy; (8) Advanced Anatomy and Physiology; (9) Operative Surgery; (10) Public Health; and (11) Tropical Diseases. Special classes are held by members of the staff for all examinations. The school possesses an Amalgamation Club, with well-fitted reading-, smoking-, and luncheon-rooms on the hospital premises. Students have the advantage of a complete library of medical and scientific books which is kept up-to-date. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean. Further information may be obtained from the Dean of the Medical School.

Staff.—Consulting Physicians: Dr. W. H. Dickinson, Dr. T. T. Whipham, Sir Isambard Owen, and Dr. Ewart. Consulting Surgeons: Mr. Pick, Mr. Haward, Sir W. Bennett, and Mr. Marmaduke Sheild. Consulting

Ophthalmic Surgeons: Mr. Brudenell Carter and Mr. Adams Frost. Consulting Aural Surgeon: Sir William Dalby. Consulting Dental Surgeon: Mr. Winterbottom. Physicians: Dr. H. D. Rolleston, Dr. Ogle, Dr. Latham, and Dr. Collier. Obstetric Physician: Dr. W. R. Dakin. Assistant Physicians: Dr. Spriggs, Dr. Jex-Blake, and Dr. Golla. Assistant Obstetric Physician: Dr. A. F. Stabb. Physician to the Skin Department: Dr. W. S. Fox. Physician Anæsthetist: Dr. F. Hewitt. Surgeons: Mr. C. T. Dent, Mr. G. R. Turner, Mr. F. Jaffrey, and Mr. Pendlebury. Ophthalmic Surgeon: Mr. H. B. Grimsdale. Assistant Ophthalmic Surgeon: Mr. R R. James. Assistant Surgeons: Mr. T. Crisp English, Mr. L. Jones, and Mr. W. F. Fedden. Surgeon to the Throat Department: Mr. H. S. Barwell. Aural Surgeon: Mr. W. C. Bull. Dental Surgeon: Mr. N. G. Bennett. Assistant Dental Surgeon: Mr. Morley.

Lecturers.—Baillie Lecturer in Physic: Dr. Howship Dickinson. Thomas Young Lecturer in Medicine: Professor William Osler. Clinical Medicine: the Physicians and Assistant Physicians. Clinical Surgery: the Surgeons and Assistant Surgeons. Principles and Practice of Physic: Dr. Rolleston, Dr. Ogle, Dr. Latham, and Dr. Collier. Tropical Medicine: Dr. T. S. Kerr. Principles and Practice of Surgery: Mr. Dent, Mr. Turner, Mr. Jaffrey, and Mr. Pendlebury. Midwifery and Diseases of Women and Children: Dr. Dakin. Assistant Lecturer on Midwifery and Diseases of Women and Children: Dr. Stabb. Vaccination: Mr. E. Climson Greenwood. Insanity and Clinical Instructor in Insanity: Dr. Seymour Tuke. Ophthalmic Surgery: Mr. Grimsdale. Diseases of the Skin: Dr. Fox. Aural Surgery: Mr. Bull. Diseases of the Throat and Nose: Mr. Barwell. Dental Surgery: Mr. Norman Bennett. Assistant Lecturer on Dental Surgery: Mr. Morley. Practical Medicine: Dr. Jex-Blake. Practical Surgery: Mr. English. Operative Surgery: Mr. L. Jones. Surgical Anatomy: Mr. Fedden. Edward Jenner Lecturer on Public Health: Dr. F. E. Fremantle. Hygiene: Dr. H. Spitta. Forensic Medicine and Toxicology: Dr. Trevor. Toxicological Chemistry: Mr. Gardner. [illegible] Dr. Spriggs. Pathology: Dr. [illegible] Slater. Assistant Lecturer or [illegible] on Clinical Pathology: Dr. [illegible] Medica and Therapeutics: Dr. Cyril Ogle. Pharmacology: Dr. Spriggs. Anæsthetics: Dr. Frederic Hewitt, M.V.O. Teacher of Anæsthetics: Dr. Blumfeld. Assistant Teachers of Anæsthetics: Dr. Powell and Mr. Longhurst. Advanced Anatomy: Mr. Jaffrey. Advanced Physiology and [illegible] Dr. Buckmaster. Advanced Chemistry and [illegible] Chemistry: Mr. Gardner. Teacher of S[illegible] Simmons. Curator of the Museum: Dr. Tr[illegible] Curator of [illegible] J. A. Torre[illegible] Curator of [illegible] Spitta. Demonstrator in Materia Medica: Dr. A. Manuel. Medical Tutor: Dr. F. W. Higgs Surgical Tutor: Mr. Ivor Back. Dean of the Medical School: Dr. E. I Spriggs.

Scholarships and Prizes.—At this school six entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*), two in Arts, 50 guineas each, Latin or Greek, French or German, English, Mathematics; (*c*) and (*d*), two in Science, 50 guineas each, Chemistry, Physics, Zoology, and Botany; (*e*) and (*f*), two University Entrance Scholarships, 70 guineas and £50 respectively, Anatomy and Physiology. The others are as follows: (*g*) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable *qualifications*, £100 per annum, Practice of Medicine, Midwifery, and Surgery; (*h*) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £40 per annum, Essay and Orig[illegible] Allingham Scholarship in Surgery for stude[illegible] more than three years interest on £18[illegible] Essay; (*j*) and (*k*), [illegible] and one in Surgery, [illegible] of not more than fi[illegible] for Proficiency in [illegible] a written Examinat[illegible] £10 10s.; (*m*) H. C. Johnson Memorial Prize, £10 10s., Practical Anatomy; (*n*) *Pollock Prize, interest on* £372, Physiology, Physiological Chemistry, and Histology; (*o*) Clarke Prize, interest on £209, Clinical Reports; (*p*) Thompson Medal, interest on £185, Clinical Reports; (*q*) Brodie Prize, interest on £220, Clinical Reports; (*r*) Webb Prize, open to perpetual pupils, interest on £1000; Bacteriology.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 608 beds.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical and medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical *council according to merit. The house physicians, of whom* there are four, hold office for six months each. The out-patient officers, who hold office for three months, attend in the out-patient or casualty department during the week and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons and there are four out-patient officers appointed each three months. The surgeons' dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments. They *hold office for three or six months.* Six are attached to each surgeon and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The college stands upon a site fronting the east gate of the hospital and is connected with it by a subway. The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club.

Medical and Surgical Staff.—Consulting Physicians: Sir Samuel Wilks, Bart., Dr. F. W. Pavy, Dr. P. H. Pye-Smith, Dr. J. F. Goodhart, and Dr. F. Taylor. Consulting Surgeons: Mr. Thomas Bryant, Sir H. G. Howse, Mr. W. H. A. Jacobson, Mr. R. C. Lucas, and Mr. Golding-Bird. Consulting Obstetric Physician: Dr. A. L. Galabin. Consulting Physician for Mental Diseases: Dr. G. H Savage. Con[illegible] aidlaw Purves. Consulting [illegible] onsulting Ophthalmic Sur[illegible] W. A. Brailey. *Consulting* [illegible] Pedley. Physicians and [illegible] ale White, Dr. G. Newton Pitt, Sir Cooper Perry, Dr. L. E. Shaw, *Dr. J. Fawcett*, Dr. A. P. Beddard, Dr. H. S. French, and Dr. A. F. Hertz. Surgeons and Assistant Surgeons: Mr. Charters J. Symonds, Mr. W. Arbuthnot Lane, Mr. L A. Dunn, Sir Alfred Fripp, C.B., K.C.V.O., Mr. F. J. Steward, Mr. Fagge, Mr. R. P. Rowlands, and Mr. Philip Turner. Obstetric Physicians: Mr. J. H. Targett and Mr. G. Bellingham Smith. Ophthalmic Surgeons: Mr. H. L. Eason and Mr. A. W. Ormond. Physician in Charge of Skin Department: Sir Cooper Perry. Physician for Mental Diseases: Dr. M. Craig. *Surgeon in Charge of Throat* Department: Mr. F. J. Steward. Surgeon in Charge of Aural Department: Mr. P. Turner. Dental Surgeons: Mr. W. A. Maggs, Mr. R. Wynne Rouw, Mr. H. L. Pillin, and Mr. M F. Hopson. Anæsthetists: Mr. G. Rowell, Dr. H. F. Lancaster, Mr. C. J. Ogle, Dr F. E. Shipway, Mr. H. M. Page, Mr. W. M. Mollison, Mr. A. R. Thompson, Mr. R. Davies-Colley, Mr. Hughes, and Dr. Cameron. Medical [illegible] and Tutors: Mr. H. C Cameron and Mr. C. H. [illegible] and Tutor: Mr. R. Davies-[illegible] Tutors: Mr. T. B. Layton [illegible] herapeutic Department: Dr. [illegible] Mr. E. W. H. Shenton, Dr. A. E. Jordan, and Dr C. J. Morton. Bacteriologist to the Hospital: Dr. J. W. H. Eyre. Resident Surgical Officer: Mr. E. L. Martyn Lobb. Hon. Librarian, Wills Library: Dr. L. E. Shaw. Lying-in Charity: Mr. Targett and Mr. Bellingham Smith. Dean of the Medical School: Dr. H. L. Eason. Warden of the College: Mr. W. M. Mollison, M.C.

(*e*) Price Scholarship in connexion with study at Oxford or Cambridge £60, Human Anatomy and Physiology; (*f*) and (*g*) two Buxton Scholarships £30 and £20 respectively, subjects of Preliminary Examination; (*h*), (*i*), and (*j*) three Scholarships for Clinical Work £20 each, Medicine, Surgery, and Obstetrics; (*k*) Sutton Prize £20, Pathology; (*l*) Duckworth Nelson Prize, biennial, £10, Pathology, Practical Medicine, and Surgery; (*m*) Letheby Prizes (3) £30, Chemistry; (*n*) and (*o*) two Scholarships £25 in Anatomy and Physiology, £20 in Anatomy and Biology; (*p*), (*q*), (*r*), (*s*), (*t*), (*u*) six Dressers' Prizes, £10 each, zeal, efficiency, and knowledge of Minor Surgery; (*v*) Hutchinson Prize, triennial, £40, Clinical Surgery; (*w*) and (*x*) two Practical Anatomy Prizes, £6 and £4 respectively; (*y*) Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; (*z*) James Anderson Prizes, £9, Clinical Medicine; (*a a*) Douro Hoare Prize, £5, Physiology; and (*b b*) Wynne Baxter Prize, £5 5*s*., Forensic Medicine.

Medical Research.—The London Hospital Medical College has lately become the trustees of a generous gift, the income of which is to be devoted entirely to the encouragement of Medical Research. Special facilities are now offered to those desirous of engaging in research at the Hospital or College and to students preparing theses for University degrees.

St. Mary's Hospital.—301 beds, 31 of which have been recently opened in the Clarence Wing and are devoted to cases requiring treatment by therapeutic inoculation. The number of in-patients treated during 1908 was 4059. The number of out-patients was 23,905 with 25,627 casualty cases, a total of 49,532. The situation of the hospital and Medical School in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it exceptionally convenient for students' rooms, a register of which is kept by the authorities for the use of students.

Laboratories, &c.—The Medical School provides for the entire curriculum. Special laboratories are in use for Biology, Chemistry, and Physics, a series of lecture theatres and laboratories for anatomy and physiology, and a spacious and well-lighted dissecting-room. The Pathological Department is under the direction of Sir Almroth Wright, F.R.S., and a block of consulting-rooms and laboratories in the New Wing of the Hospital has been equipped for the department of Therapeutic Inoculation to meet the increased amount of work in that department. During the past year 511 patients have received treatment in the department. A special laboratory is provided for the study of chemical pathology.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, and four obstetric officers are appointed in each year and receive board and lodging in the hospital. Two resident anæsthetists are appointed in each year and receive a salary at the rate of £100 per annum, with board and lodging. Two casualty house surgeons are appointed in each year upon the same conditions. Several assistants in the department of Therapeutic Inoculation are appointed annually at salaries of £100 per annum and upwards, the total sum available for salaries of assistants in this department being £1600 per annum. In addition to the above, the senior appointments, medical and surgical registrar, casualty physician, demonstrator of anatomy, physiology, and biology are made annually.

Clubs, &c.—The amalgamated clubs include all the various athletic clubs, as well as the rifle club, medical society, &c. There is a students' club on the Hospital premises, the membership of which is included in the amalgamated clubs. The athletic clubs' ground (eight acres) is situated at North Kensington and can be reached in 20 minutes from the Medical School. It consists of Rugby and Association football grounds, tennis courts, and a large cricket pitch.

Special Tuition.—In addition to systematic courses of lectures and demonstrations special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

Preliminary Scientific Course.—Special classes, including lectures and laboratory work, are held throughout the year under recognised teachers of the University of London.

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 60 guineas (£63) paid in one sum or by payment of two annual instalments of 35 guineas (£36 15*s.*) and 30 guineas (£31 10*s.*) respectively. University students who have not completed their examination in Anatomy and Physiology pay an annual fee of 25 guineas (£26 5*s.*) until they have passed these examinations, and then pay the composition fee. Separate courses of lectures, laboratory work, or hospital practice may be taken. The School Calendar and full information can be obtained from the Secretary, St. Mary's Hospital Medical School, Paddington, W.

Staff.—Consulting Physicians: Dr. Cheadle and Dr. Lees. Consulting Surgeons: Mr. A. T. Norton, Mr. Edmund Owen, Mr. Herbert Page, Mr. G. P. Field (Aural), Sir G. Anderson Critchett, Bart. (Ophthalmic), Sir Malcolm Morris (Skin), Mr. Morton Smale (Dental), and Dr. Scanes Spicer (Throat). Consulting Anæsthetist: Mr. Henry Davis. Physicians: Dr. Sidney Phillips, Dr. A. P. Luff, and Dr. H. A. Caley. Surgeons: Mr. A. J. Pepper, Mr. J. Ernest Lane, and Mr. H. Stansfield Collier. Physicians in charge of Out-Patients: Dr. Wilfred Harris, Sir John Broadbent, Bart., and Dr. W. H. Willcox. Surgeons in Charge of Out-Patients: Mr. V. Warren Low, Mr. W. H. Clayton-Greene, and Mr. Maynard Smith. Physician-Accoucheur: Dr. Montagu Handfield-Jones. Physician-Accoucheur in charge of Out-Patients: Dr. W. J. Gow. Physician in charge of Children's Department: Dr. Sidney Phillips. Ophthalmic Surgeon: Mr. H. E. Juler. Assistant Ophthalmic Surgeon: Mr. Leslie Paton. Physician to the Skin Department: Dr. Graham Little. Dental Surgeon: Mr. W H. Dolamore. Surgeons to the Ear, Nose, and Throat Department: Dr. G. William Hill and Mr. C. I. Graham (assistant). Administrators of Anæsthetics: Dr. Blumfeld, Mr. Collum, and Mr. Henry Chaldecott. Director in Medical Charge of Inoculation Department: Sir Almroth Wright. Dean: Mr. W. H. Clayton-Greene.

Lecturers.—Clinical Medicine: Dr. Sidney Phillips. Clinical Surgery: Mr. A. J. Pepper. Medicine: Dr. A. P. Luff and Dr. H. A. Caley. Surgery: Mr. J. Ernest Lane and Mr. H. Stansfield Collier. Practical and Operative Surgery: Mr. V. W. Low and Mr. Maynard Smith. Pathology: Sir A. E. Wright and Dr. Spilsbury. Bacteriology: Sir A. E. Wright and Captain S. R. Douglas (assistant lecturer). Pathological Chemistry: Dr. W. H. Willcox. Midwifery and Gynæcology: Dr. M. Handfield-Jones. Materia Medica and Therapeutics: Dr. H. A. Caley. Forensic Medicine: Dr. Willcox. Neurology: Dr. Harris. Descriptive and Surgical Anatomy: Mr. W. H. Clayton-Greene. Demonstrators: Mr. C. I. Graham and Dr. V. Z. Cope. Physiology and Histology: Dr. N. H. Alcock. Biology: Dr. W. G. Ridewood. Demonstrator: Mr. T. Reed. Chemistry: Dr. G. Senter. Physics: Mr. W. H. White. Hygiene and Public Health: Dr. W. H. Willcox. Mental Diseases: Dr. Theo B. Hyslop. Diseases of the Eye: Mr. Leslie Paton. Diseases of the Ear, Nose, and Throat: Dr. G. William Hill. Diseases of the Skin: Dr. Graham Little. Dental Surgery: Mr Dolamore. Medical Tutors: Sir John Broadbent and Dr. Willcox. Surgical Tutors: Mr. V. Warren Low, Mr. Clayton-Greene, and Mr. Maynard Smith. Obstetric Tutor: Dr T. G. Stevens. Medical Registrar: Dr. R. H. Miller. Surgical Registrar: Mr. M. Fitzmaurice Kelly. Department for Nervous Diseases: Dr. W. J. Harris. Practical Pharmacy: Mr. E. A. Andrews (demonstrator). School Secretary: Mr. B. E. Matthews.

Scholarships and Prizes.—The money value and subjects of examination of these are as follows: (*a*), (*b*), (*c*), and (*d*), four Natural Science Scholarships awarded by competition, £145, £50, £50, and £25 respectively; (*e*) and (*f*), two University Scholarships open to students from any British University, £52 10*s*. each, Natural Science, (*g*) Epsom College Scholarship awarded by nomination, representing free tuition; (*h*) Gold Medal, £20, an Essay on Some Special Point in Clinical Medicine; (*i*), (*j*), and (*k*), three General Proficiency Scholarships, £20 each, one in Advanced Anatomy, Physiology, and Histology, one in Midwifery, Materia Medica, Pathology, and Forensic Medicine, and one in Medicine, Surgery, Hygiene, and Mental Diseases; (*l*) Dermatology Prize, awarded twice in each year, £5 5*s*.; (*m*) Meadows' Prize, awarded in alternate years, £8, Obstetrics; (*n*) and (*o*), Clinical Medicine and Clinical Surgery Prizes, £5 5*s*. each, Clinical Reports by Students of third and fourth years; (*p*) nine Winter Session Prizes, £3 3*s*. each, subjects of the medical curriculum; and (*q*) nine Summer Session Prizes, £2 2*s*. each, subjects of the medical curriculum

MIDDLESEX HOSPITAL.—The hospital contains 345 beds, which includes a special wing for patients suffering from cancer, consisting of four wards, containing 45 beds; here cancer patients are received and attended for a period limited only by the duration of their disease. The number of patients treated last year were: Out-patients, 47,880; in-patients, 3859. Cancer: Out-patients, 87; in-patients, 159.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects included in the examinations in Medicine and Surgery in the United Kingdom and for the diploma in Public Health; and ample laboratory and class-room accommodation is provided for the teaching of the various subjects of the curriculum and for original research in Medicine, Pathology, or Bacteriology. A Maternity Ward in which students receive systematic instruction in Obstetric Medicine has recently been added to the hospital.

Special Classes are held to prepare students for the Inter. M.B. (Lond.) Examination and for the Primary and Final Examinations for the diploma of F.R.C.S. Eng.

Attached to the Cancer Wing of the hospital is a special research laboratory and in connexion with this there are the Emden Cancer Research Scholarship, the Richard Hollins Research Scholarship, the Salters' Company Cancer Research Scholarship, and a Cancer Research Scholarship.

The Bacteriological and Public Health Laboratory for Women Medical Practitioners and Women Students, situated at 27, Mortimer-street, W., is in connexion with this hospital, and is under the direction of Mr. A. G. R. Foulerton, assisted by Dr. Hilda K. Whittingham. This laboratory, for the maintenance of which a private guarantee fund has been raised by some supporters of the hospital who are anxious to provide facilities for the special training of women in Public Health work, has been added to the Middlesex Hospital Medical School for the purposes of providing instruction for women medical practitioners for the examinations for the Diploma in Public Health and for the M.D. in State Medicine of the University of London, and of affording facilities to them and other women students for carrying out research work in Public Health, Bacteriology, and General Pathology.

Hospital Appointments.—All hospital appointments are allotted to students without any extra fee. The following 18 resident appointments—six house physicians, six house surgeons, two obstetric house physicians, two casualty medical officers, and two casualty surgical officers—are annually filled from the pupils of the hospital, each appointment extending over six months.

A *Residential College* to accommodate a limited number of students adjoins the hospital. Breakfast, luncheon, and dinner are supplied in the College Hall at moderate charges.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, the cricket club, the football clubs, the athletic clubs, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. The athletic ground, which is eight acres in extent, is situated within easy access at Wormwood Scrubs.

Fees.—The Composition Fee for the entire curriculum is 135 guineas, or 145 guineas if paid in three instalments. The fee for London University students is 145 guineas; for those who have passed the Preliminary Scientific 120 guineas. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M.B. Examination are received on special terms.

Lecturers.—Winter Session: Anatomy: Dr. Cameron. Demonstrator: Dr. Gladstone. Embryology: Dr. Gladstone. Biology and Physiology: Mr. Goodall. Demonstrator: Mr. Earle. Chemistry: Dr. Kellas. Emeritus Lecturer in Medicine: Sir R. D. Powell, Bart., M.D. Medicine: Dr. Pasteur and Dr. Wynter. Practical Medicine: Dr. Voelcker. Emeritus Lecturer in Surgery: Sir Henry Morris, Bart. Surgery: Mr. Pearce Gould, Mr. Bland-Sutton, and Mr. Murray. Practical Surgery: Mr. Kellock. Operative Surgery: Mr. Kellock. Practical Midwifery: Dr. Bonney. Pathology: Dr. Voelcker. Forensic Medicine and Toxicology: Dr. Wethered. Clinical Lectures in Medicine: The Physicians. Clinical Lectures in Surgery: The Surgeons. Clinical Lectures on Diseases of the Ear, Throat, and Nose: Mr. S. Paget. Lectures in Ophthalmology: Mr. Lang. Lectures in Dental Surgery: Mr. Nowell. Public Health and Bacteriology: Mr. Foulerton. Summer Session: Pharmacology and Therapeutics: Dr. R. A. Young. Midwifery: Dr. Comyns Berkeley. Pathological Histology: Dr. Voelcker. Practical Toxicology: Dr. Kellas. Mental Diseases: Dr. Mickle. Lectures in Dermatology: Dr. Pringle. Anatomy, Chemistry, and Physiology: as in Winter Session. Tutors—Medicine: Dr. Campbell Thomson; Surgery: Mr. Handley; Obstetrics: Dr. Taylor.

Staff.—Consulting Physicians: Dr. W. Cayley, Dr. Sidney Coupland, and Sir J. K. Fowler, D [illegible] Physicians to Out-patients: Dr. A. P. Voelcker, Dr. F. J. Wethered, and Dr. H. Campbell Thomson (Dean of the Medical School). *Assistant Physician: Dr. R. A. Young.* Consulting Physician to the Skin Department: Dr. R. Liveing. Physician to the Skin Department: Dr. J. J. Pringle. Consulting Obstetric Physician: Dr. W. Duncan. Obstetric Physician: Dr Comyns Berkeley. Assistant Obstetric Physician: Dr. Victor Bonney. Consulting Surgeons: Sir Henry Morris, Bart., and Mr. Clark. Surgeons: Mr. Gould, Mr. Bland-Sutton, and Mr. Murray. Surgeon to Out-patients: Mr. Kellock. Assistant Surgeons: Mr. Handley and Mr. Gordon Taylor. Ophthalmic Surgeon: Mr. W. Lang. Aural Surgeon: Mr. S. Paget. Consulting Dental Surgeon: Mr. W. Hern. Dental Surgeon: Mr. Nowell. Assistant Dental Surgeon: Mr. H. W. Turner. Curator of the Museum and Pathologist: Dr. Lakin. Registrars: Dr. Otto May, Mr. Rowntree, and Dr. Taylor. Resident Medical Officer: Mr. A. E. Johnson. Anæsthetists: Mr. T. G. A. Burns and Mr. H. P. Noble. Assistant Anæsthetist: Mr. H. Charles.

Scholarships and Prizes.—Holders of the Entrance Scholarships are required to become general students of the school. The money value and subjects of examination are as follows: (*a*), (*b*), and (*c*), three Entrance Scholarships, £100, £50, and £25 respectively; (*d*) Entrance Scholarship for Students from Oxford or Cambridge, £50, Anatomy and Physiology, including Histology; (*e*) Freer Lucas Scholarship for Students of Epsom College, on nomination of Headmaster, £126; (*f*) and (*g*), two Broderip Scholarships for Senior Students, £60 and £40 respectively, Clinical subjects; [illegible]

Surgical Pathology and Bacteriology; (*m*) second year's Exhibition, £10 10*s*., Anatomy and Physiology; (*n*) "Emden" Cancer Research Scholarship tenable for three years, £100; (*o*) Richard Hollins Research Scholarship, £105; (*p*) Salters' Company Cancer Research Scholarship, £100; and (*q*) Cancer Research Scholarship, £60.

ST. THOMAS'S HOSPITAL.—This hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 600 beds. The in-patients last year numbered 6972, whilst the number of attendances as out-patients, including the casualty and light departments, was 226,239. There are departments for the treatment of women, children, the eye, ear, nose and throat, skin, and teeth. Departments for light treatment, x rays, and physical exercises are also special features. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day except Saturdays at 2 P.M. Clinical teaching in the wards, out-patients' and special departments is available every day of the week. Clinical lectures are delivered every Wednesday and Thursday during the sessions. All appointments in the hospital are open to students without extra fee. Casualty officers and resident anæsthetists, house physicians, house surgeons, obstetric house physicians, ophthalmic house surgeons, and out-patient officers are appointed and hold office for six months. They are provided with rooms and commons in the hospital free of expense. Clinical assistants to all the special departments are appointed every three months; they are non-resident. A resident assistant physician and a resident assistant surgeon, at a salary of £100 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £100 and the two latter £50. An assistant in the clinical laboratory, at a salary of £100 per annum, and an assistant pathologist, at a salary of £125, are from time to time appointed. Appointments open to students before qualification: Clinical clerks and dressers for in- and out patients are selected from students who have completed their third year's work. The accident dressers are provided with board and lodging during their periods of special duty. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn for three weeks on maternity duty under proper supervision, and is practically instructed in the administration of anæsthetics by one of the hospital anæsthetists. On completion of his term as clerk or dresser he is expected to fill appointments in one or more of the special departments. In their earlier years of study students are selected as assistants to the lecturers in the preliminary and intermediate subjects The Medical School is fully equipped for the teaching of all subjects of the curriculum. A fine museum and large library are at the disposal of the students. There are three lecture theatres, an unusually large and well-ventilated dissecting-room, and special laboratories for biology, chemistry, physics, physiology, and pathology. The post-mortem room, where demonstrations are given every day, is ventilated by the electric fan and provided with cold storage. The Students' Club comprises a spacious restaurant and magnificent smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The athletic ground of the Amalgamated Clubs at Chiswick is over nine acres in extent and is easily accessible from Waterloo Station. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. There is a special course for the Diploma in Public Health. The hospital is easily accessible from all parts. It is close to the Waterloo and Westminster Bridge Stations (L. & S.W., Bakerloo, and District Railways). Electric trams which pass the doors connect it with all parts of South London. A register of lodgings and a list of medical men and others who are willing to receive boarders is kept by the secretary, Mr. G. Q. Roberts, who will give any further information required.

Fees.—The annual composition fee is 30 guineas—in addition to a fee on entrance. Post-graduate study is afforded to qualified practitioners by a joint ticket which admits to the practice of 14 hospitals (general and special) on terms which may be ascertained from the secretary.

Staff.—Consulting Physicians: Dr. Harley and Dr. Payne. Consulting Surgeons: Mr. S. Jones and Mr. B. Pitts. Consulting Obstetrical Physician: Dr. Gervis. Consulting Ophthalmic Surgeons: Mr. Liebreich and Mr. Nettleship. Consulting Anæsthetist: Mr. W. Tyrrell. Consulting Dentist: Mr. C. E. Truman. Physicians: Dr. Sharkey, Dr. Acland, Dr. Hawkins, Dr. Mackenzie, and Dr. Turney. Surgeons: Mr. Clutton, Mr. G. H. Makins, C.B., Mr. Battle, Mr. Ballance, M.V.O., and Mr. Robinson. Physicians to Out-patients: Dr. Perkins, Dr. Colman, Dr. Box, and Dr. Russell. Surgeons to Out-patients: Mr. C. S. Wallace, Mr. E. M. Corner, Mr. Sargent, and Mr. C. A. R. Nitch. Obstetric Physician: Dr. Tate. Obstetric Physician to Out-patients: Dr. Fairbairn. Ophthalmic Surgeon: Mr. Lawford. Ophthalmic Surgeon to Out-patients: Mr. Fisher. Physician for Diseases of Children: Dr. Box. Surgeon for Diseases of Children: Mr. C. A. R. Nitch. Surgeon for Diseases of the Throat: Mr. H. B. Robinson. Physician for Diseases of the Skin: Dr. E. Stainer. Surgeon for Diseases of the Ear: Mr. Marriage. Dental Surgeons: Mr. J. G. Turner and Mr. G. L. Bates. Resident Assistant Physician: Dr. Cassidy. Resident Assistant Surgeon: Mr. L. E. C. Norbury. Anæsthetists: Dr. H. Low, Dr. Bevan, Dr. Mennell, and Dr. Hedley. Pharmaceutist: Mr. J. A. Jennings. Curator of Museum: Mr. S. G. Shattock. Director of Laboratories: Mr. L. S. Dudgeon. Superintendent of X Ray Department: Dr. Greg.

Lecturers and Demonstrators.—Anatomy: Mr. F. G. Parsons, with Mr. P. W. G. Sargent and Mr. C. A. R. Nitch. Chemistry: Dr. Le Sueur. Physiology: Dr. J. Mellanby. Biology: Mr. Cutting. Pathology and Bacteriology: Mr. Shattock and Mr. Dudgeon. Surgery: Mr. Battle and Mr. Ballance. Medicine: Dr. Sharkey and Dr. Hawkins. Practical and Operative Surgery: Mr. Robinson, Mr. Wallace, and Mr. Corner. Comparative Anatomy: Mr. Parsons. Applied Anatomy: Dr. Box. Anæsthetics: Dr. Low. Physics: Mr. Brinkworth. Clinical Medicine: The Physicians. Clinical Surgery: The Surgeons. Midwifery and Diseases of Women: Dr. Tate and Dr. Fairbairn. Diseases of the Eye: Mr. Lawford and Mr. Fisher. Pharmacology and Therapeutics: Professor Dixon. Throat Disease: Mr. H. B. Robinson. Physiological Demonstrator: Mr. E. Mellanby. Obstetrical Demonstrators: Dr. Fairbairn and Dr. Hedley. Practical Medicine: Dr. Perkins, Dr. Colman, Dr. Box, and Dr. Russell. Surgical Classes: Mr. Wallace, Mr. Corner, Mr. Sargent, Mr. Fisher, and Mr. Shattock. Forensic Medicine and Toxicology: Dr. Colman and Dr. Haas. Mental Diseases: Dr. R. Percy Smith. Public Health: Professor Simpson. Tropical Medicine: Dr. Sandwith. Instruction in Vaccination by Dr. Cope. Dean of the School: Mr. Cuthbert Wallace. Sub-Dean: Dr. C. R. Box. Secretary: Mr. G. Q Roberts, from whom any further information may be obtained.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first medical examination; two in Natural Science of the value of £150 and £60 respectively, to be taken out in tuition fees; and the University Scholarship of £50 in Anatomy, Physiology, and Chemistry. The money value and subjects of examination of the remainder are as follows:—(*a*) and (*b*), two college prizes for second-year students, £10 and £5 respectively; (*c*) William Tite Scholarship for second-year students, £25; (*d*) and (*e*), Musgrove Scholarship or (alternately) Peacock Scholarship each for third-year students and tenable for two years, £35 each; (*f*) one College Prize for third-year students, £10; (*g*) three College Prizes for fifth year students of £10 each and three of £5 each; (*h*) Cheselden Medal, Surgery and Anatomy; (*i*) Mead Medal, Medicine, Pathology, and Hygiene; (*j*) Toller Prize, Medicine, Pathology, and Hygiene; (*k*) Bristowe Medal, Pathology and Morbid Anatomy; (*l*) Solly Medal and Prize, biennially, Surgical Reports; (*m*) Medal for the most distinguished fifth-year student; (*n*) Wainwright Prize, Medicine, Pathology, and Hygiene; (*o*) Hadden Prize, Pathology; (*p*) Beaney Scholarship, £50 biennially, Surgery and Surgical Pathology; (*q*) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (*r*) Grainger Testimonial Prize, £15, Anatomy and Physiology; (*s*) Salters' Company Research Fellowship, tenable for three years, £100 annually, Pharmacology; and (*t*) Louis Jenner Research Scholarship Tenable for two years, £60 annually, Pathology.

UNIVERSITY COLLEGE, LONDON.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Departments of Hygiene and Public Health and of Pathological Chemistry (Post-graduate Study).

The new Institute of Physiology, opened by the Right Hon. R. B. Haldane on June 18th last, the new Department of Botany, and the new Department of Pharmacology will be ready for the use of students in October.

Faculty of Medical Sciences.—Composition fees.—For the courses required by the University of London. 1. For the First Medical (Preliminary Scientific) Course, 26 guineas, entitling to one attendance and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for one session. 2. For the Second Medical (Intermediate) Course, 58 guineas if paid in one sum; 63 guineas if paid in two instalments of 32 guineas and 31 guineas respectively. This fee entitles to attendance on Anatomy and Physiology during three years and to one attendance on Organic Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for two sessions.

For the medical education required by the Examining Board in England, and the Society of Apothecaries. First examination, Parts I., II., III., 21 guineas, entitling to one attendance and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for one session. First examination, Part IV., and second examination, 58 guineas if paid in one sum, and 63 guineas if paid in two instalments of 32 guineas and 31 guineas respectively. This fee entitles to attendance [illegible] Society [illegible], ground [illegible]

Professors and Lecturers.—1. First Medical (Preliminary Scientific) Course.—Chemistry:—Professor: Sir William Ramsay, K.C.B., F.R.S.; assistant professors: E. C. C. Baly, F.I.C., F.R.S., Samuel Smiles, D.Sc., and N. T. M. Wilsmore, D.Sc.; *assistants: R. W. Gray, Ph.D., and* W. B. Tuck, B.Sc.; demonstrator: H. T. Clarke. Physics:—Professor: F. T. Trouton, F.R.S.; assistant professor: A. W. Porter, B.Sc.; assistants: N. Eumorfopoulos, B.Sc., A. O. Rankine, B.Sc. Botany:—Professor: F. W. Oliver, M.A., D.Sc.; assistant professor: F. E. Fritsch, D.Sc., Ph.D.; assistant: T. G. Hill, A.R.C.S. Zoology:—Professor: J. P. Hill, D.Sc.; assistants: W. Woodland, D.Sc., and C. H. O'Donoghue, B.Sc. 2. Second Medical (Intermediate) Course.—Anatomy:—Professor: G. D. Thane, LL.D.; assistant and curator of the museum: G. S. Hett, M.B.; demonstrators: G. E. Waugh, B.S., F.R.C.S., H. T. Mant, M.S., F.R.C.S.; assistant demonstrators: J. H. Farbstein, M.B., B.S.; W. E. Haigh, M.R.C.S., L.R.C.P. Physiology:—Professor: E. H. Starling, M.D., F.R.S.; assistant professors: W. M. Bayliss, D.Sc., F.R.S., G. A. Buckmaster, M.D.; assistant: R. H. Aders-Plimmer, D.Sc.; lecturers: J. H. Parsons, F.R.C.S. W. Page May, M.D., D.Sc., S. B. Schryver, D.Sc. Pharmacology:—Professor: A. R. Cushny, M.D., F.R.S. Organic Chemistry:—Professor: J. N. Collie, F.R.S.; assistant: Samuel Smiles, D.Sc.

Scholarships and Prizes.—At University College the various exhibitions, prizes, medals, &c., which are given have a relation to medical study. The first two items on the present list require a complete intermediate course at University College. The money value and subjects of examination are as follows:—(*a*) and (*b*) tw [illegible] Chemistry, [illegible] Memorial Pr [illegible] Chemistry; [illegible] (*c*) Sharpey [illegible] Sciences; (*f*, [illegible] sional men, by nomination, tenable for two years, £16 a year; and (*g*) five Gold and five Silver Medals awarded annually in various departments.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: H. Batty Shaw, M.D., F.R.C.P. Vice-Dean: Raymond Johnson, B.S., F.R.C.S. Secretary: L. R. Thomas. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. Course, 80 guineas if paid in one sum, 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. Students who obtain a medical qualification within three years of the time of commencing this course are not required to pay an additional fee for further attendance. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries.

There are 300 beds in the hospital and 51,369 patients were treated last year.

Special Departments, Clinical or Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology are admitted to work in the laboratories of the school by the Professor. A special course of instruction is given for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies; also special courses of [illegible] the [illegible] eth, [illegible] and in Clinical and Tropical Pathology. These courses are designed for senior students and graduates.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians and house surgeons, four senior and four junior obstetric assistants are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by *senior students of the hospital:* 1. *The Resident Medical* Officer. This officer is appointed for a period of two years and is chose [illegible] of the hospi [illegible] from among [illegible] 3. The Obst [illegible] and a Casu [illegible] period of six months. 5. Deputy Anæsthetists. During the absence of one or another of the Anæsthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

School Buildings and Equipment.—The new buildings for University College Hospital, completed by the generosity of the late Sir Blundell Maple, Bart., were opened by H.R.H. the Duke of Connaught on Tuesday, Nov. 6th, 1906. The new buildings for the Medical School, erected through the generosity of Sir Donald Currie, are now in occupation and contain accommodation for undergraduate and postgraduate students in all departments of medical study sub- [illegible] —The Museum, a spacious and well-lighted room, is open for study from 8 A.M. to 5 P.M. The collection is divided into three sections—medical, surgical, obstetrical and gynæcological. The surgical section is a particularly complete one and contains examples of every variety of surgical disease and injury. Diseases of the skin are well illustrated by a number of wax models which are conveniently displayed in glass cases. The obstetrical and gynæcological section is very complete. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students *on application to the Curator. The Museum contains* 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston. It is also furnished with a small theatre, where separate demonstrations in each subject are given several times a week by members of the teaching staff.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M.; Saturdays 9 A.M. to 1 P.M. It contains about 10,000 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. *All Students of the Medical School are* eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine and the allied sciences and for the exhibition of cases of pathological interest. One room in the Medical School is [illegible] and is provided with [illegible] The society also posse [illegible] collection for the use [illegible] the society includes [illegible] management of three [illegible] Medical School, which [illegible] zines, writing materials, chess- and draught-boards, &c., solely for the use of its members. The society also superin- [illegible] *of the Medical School.* [illegible] in conjunction with the [illegible] of London University [illegible] Western Railway station at Perivale and is within easy reach of the Hospital and School, *about 35 minutes by train from* Gower-street station. The following clubs are connected with *the society: Cricket* Club, Rugby Football Club, Association Football Club, Hockey Club, and Lawn-Tennis Club. The society also has the use of the College racquets and fives courts for its members. The affairs of the society are conducted by a committee elected annually by the members.

Residence of Students.—A register of boarding residences is kept in the office of the Medical School for the convenience of Students; these residences are not under the control of the school authorities. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Private Instruction.—Gentlemen who desire assistance in their studies should consult the Dean, Professors, or Lecturers.

Hospital Staff.—Consulting Physicians: Sir W. R. Gowers, Dr. H. C. Bastian, Sir J. Williams, Bart., Dr. S. Ringer, and Dr. F. T. Roberts. Physicians: Sir Thomas Barlow, Bart., Dr. J. Rose Bradford, Dr. Sidney Martin, Dr. J. Risien Russell, and Dr. H. Batty Shaw. Assistant Physicians: Dr. F. J. Poynton and Dr. C. Bolton. Obstetric Physicians: Dr. H. R. Spencer and Dr. G. F. Blacker. Consulting Surgeons: Sir John Tweedy (Ophthalmic) and Sir Victor Horsley. Surgeons: Mr. A. E. Barker, Mr. R. J. Godlee, Mr. Bilton Pollard, and Mr. Raymond Johnson. Assistant Surgeons: Mr. Wilfred Trotter and Mr. H. Morriston Davies. Ophthalmic Surgeon: Mr. Percy Flemming. Assistant Ophthalmic Surgeon: Mr. J. H. Parsons. Professor and Lecturer on Public Health: Dr. Henry R. Kenwood. Dental Surgeon: Mr. Sidney Spokes. Assistant Dental Surgeon: Mr. H J. Relph. Anæsthetist: Dr. Dudley Buxton. Assistant Anæsthetists: Dr. H. J. Scharlieb and Mr. A. Beresford Kingsford. Surgical Registrar: Mr. O. L. Addison. Resident Medical Officer: Dr. A. M. H. Gray. Pathologist: Dr. F. H. Thiele. Electro-therapeutist: Mr. E. S. Worrall. Radiographer: Mr. R. H. Cooper. Pharmacist: Mr. R. R. Bennett.

Teaching Staff.—Medicine—The Principles and Practice of Medicine: Dr. J. Rose Bradford. Clinical Medicine: Sir Thomas Barlow, Dr. J. Rose Bradford, Dr. Sidney Martin, Dr. J. Risien Russell, Dr. H. Batty Shaw, Dr. F. J. Poynton, and Dr. C. Bolton. Therapeutics: Dr. H. Batty Shaw. Surgery—The Principles and Practice of Surgery: Mr. Arthur E. J. Barker. Clinical Surgery: Mr. Arthur E. J. Barker, Mr. Rickman J. Godlee, Mr. Bilton Pollard, Mr. Raymond Johnson, Mr. Wilfred Trotter, and Mr. H. Morriston Davies. Practical Surgery: Mr. Raymond Johnson and Mr. H. Morriston Davies. Surgical Anatomy: Mr. G. E. Waugh. Midwifery and Gynæcology—Dr. H. R. Spencer. Clinical Midwifery and Gynæcology: Dr. H. R. Spencer and Dr. G. F. Blacker. Diseases of Childhood: Dr. H. Batty Shaw, Mr. Raymond Johnson, Mr. Percy Flemming, and Mr. Herbert Tilley. Pathology and Morbid Anatomy—General Pathology: Dr. Sidney Martin. Practical Pathology: Dr. D. N. Nabarro, Assistant Professor; and Dr. A. C. Stevenson, Assistant Bacteriologist. Laboratory and Special Instruction: Dr. Sidney Martin. Chemical Pathology and Clinical Pathology and Post-mortem Examination: Dr. F. H. Thiele. Museum of Pathological Anatomy: Mr. T. W. P. Lawrence, Curator. Forensic Medicine: Dr. J. S. Risien Russell. Diseases of the Eye—Ophthalmic Medicine and Surgery: Mr. Percy Flemming. Clinical Ophthalmology: Mr. Percy Flemming and Mr. J. Herbert *Parsons. Diseases of the* Ear and Throat: Mr. Herbert Tilley. Mental Physiology and Mental Diseases: Dr. W. Julius Mickle. Dental Surgery: Mr. Sidney Spokes and Mr. H. J. Relph. Instruction in the Use of Anæsthetics: Dr. Dudley W. Buxton. Electro-therapeutic Department: Mr. E. S. Worrall. Radiographic Department: Mr. R. Higham Cooper. Practical Pharmacy: Mr. R. R. Bennett.

Scholarships and Prizes.—At this School the first two items in the present list require a complete course at University College and University College Hospital Medical School; the second two require a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and nomination by Epsom College; (*c*) and (*d*) two Entrance Exhibitions, 80 guineas each, Anatomy and Physiology; (*e*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*f*) Atchison Scholarship tenable for two years, £55 per annum; (*g*) Filliter Exhibition, £30, Pathology; (*h*) Erichsen Prize, £10 10*s*., Practical Surgery; (*i*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*j*) two Liston Gold Medals for Clinical Surgery; (*k*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*l*) Tuke Silver and Bronze Medals for Pathology.
